— LIVE STOCK RETURNS.—As to the various kinds of live stock there appears to be a slight decline in agricultural horses, caused, it is stated, by the number of unlet farms, and also a decrease in brood mares and young horses, for which the demand has not been so great recently. Moreover, the stock of horses had increased up to last year, when the numbers were larger than in any year since 1870. The imports of horses from abroad were 26,000 in 1878, 15,000 in 1879, and only 6,600 in the first eight months of the present year. As regards horned cattle, milch cows have decreased less than 1 per cent., but other cattle show an increase of nearly 2 per cent., so that the total number of horned cattle in Great Britain is this year 5,912,000 as compared with 5,856,000 in 1879. Sheep in the country have suffered an important decline of nearly a million, chiefly owing, the collectors state, to the losses by disease, and lambs have also decreased more than half a million, partly, it is stated, from the weak condition of the ewes. The stock of sheep and lambs is now only 26,619,000—which appears to be a very insufficient number considering the additional permanent pastures of late years. It may be remarked that these great losses in sheep and lambs have occurred only in England and Wales, the counties of Scotland with few exceptions showing a small increase in sheep and a considerable one in lambs, while the northern border counties of England have also escaped in great measure. Pigs have further decreased by 91,000 since 1879, and by 483,000 since 1878, the competition of American bacon being stated to make pig-keeping less profitable than formerly, while, as before mentioned, the sanitary regulations in populous places tend also to diminish their numbers.

— ACREAGE OF GREEN CROPS.—As regards the green crops we find from the recently published agricultural returns an increase of 10,000 acres planted with Potatoes, and the area 551,000 acres is nearly equal to the figure of ten years ago. Turnips and Swedes were returned as grown on 2,024,000 acres, a small increase from 1879, but Mangolds show a decrease of nearly 6 per cent. from last year. Cabbage, Kohl Rabi, &c., of 4 per cent.; and Vetches, Lucerne, and other green crops of more than 15 per cent., the acreage this year being only 380,000, making the total area under green crops 3,477,000 acres, or 2 per cent. less than in 1879. Green crops on the whole have shown little change during the last ten years, but the present year's figures are less than in any year since 1868. Flax has increased somewhat from the average of the last five years, but the area, 9000 acres, is still less than half the acreage grown ten years ago. Hops were planted on 67,000 acres, about the same area as in 1879. A return was added last year, and is continued this year, to show in greater detail than in counties the districts in which the Hops are grown. Bare fallow in Great Britain has further increased from 721,000 acres to 812,000 acres, and has this year taken a larger area than in any year since 1870, when there were only 610,000 acres in fallow. The depression in agriculture and the number of farms unlet and temporarily farmed by their owners are stated by the collecting officers as the chief reasons of so much land being uncropped, and the foul state of the land is also noticed in some districts. Clover and rotation Grasses have varied little in their acreage from 1879, showing 4,434,000 acres at the present time. Permanent pasture and meadow have increased by 260,000 acres since last year, and now amount to 14,427,000 acres, or nearly 45 per cent. of the cultivated area of Great Britain.

— HOG PRODUCTS OF AMERICA.—Pork-packing in the west has, says the "American Cultivator," increased from 1,652,220 head to over 6,000,000, in round numbers, during the past thirty years. The old "razor-backs" of the generation passing away are giving place to modern improved breeds—viz., the best strains of Poland China, Chester White, Berkshire, &c. Of barrelled pork packed in the country about 70 per cent. is put up in six cities—Chicago, Cincinnati, St. Louis, Indianapolis, Milwaukee, and Louisville. Since March 1st, and including twenty-eight weeks, the number of hogs packed aggregate 4,310,901, against 2,885,658 in the same time last year; and the winter packing figures up 6,950,000 against 7,480,000. Total packing since November 1st, 11,260,000, against 10,385,000. Exports since November 1st—of meats, 785,000,000, against 766,200,000; lard, 347,000,000 lbs., against 304,100,000; total product, 1,132,000,000 lbs.

against 1,070,600,000 lbs. These are royal figures, expressive of the American trade in hog products. Hogs have declined about 20 cents. per 100 lbs. in the Chicago market, and the receipts at that point are running steadily below the corresponding time last year.

THE BEE SEASON OF 1880.

THE bee season in Scotland has been, I believe, on the whole satisfactory to apiculturists, especially to such as have apiaries within easy reach of the Heather, that best of honey-producing autumn plants. But for this, however, the results in many districts would have been far from favourable. Such, at least, has been our experience in Midlothian.

The past spring opened promising enough considering the sad condition in which the previous autumn found our stocks both as regards population and stores. Inauspicious weather supervened, however, and being somewhat prolonged breeding went on so slowly that in April little progress was perceptible, the older bees disappearing faster than the accession of the young from the brood cells, so that the weaker hives dwindled away simply from want of a sufficiency of bees to carry on the necessary work. More favourable weather followed in May and June, and breeding was again in full progress. Still swarming was not so general as in ordinary seasons, and honey-gathering was extremely meagre. Summer honey-yielding blossoms were not so plentiful as usual, and as time went on appearances became even more gloomy; so that bee-keepers like myself, who do not benefit by a proximity to white Clover-growing pasture lands, had a poor return of flower honey, and in some cases feeding had actually to be resorted to to prevent starvation. But another chance still remained. The Heather season was at hand. August commenced under auspicious circumstances; good weather set in early in that month. The bees were forthwith dispatched with all haste to seek their fortune among the Pentland Hills, and retrieve if possible the shortcomings of the summer, and not for many years has there been a fairer prospect of success. The Heath was rich and luxuriant, its purpled blossoms abundant and opening. Could the result under such circumstances, and with a continuance of good weather, be doubted? In a little over four weeks these comparatively empty hives were brought back to their summer stances laden with golden stores, some having gathered from 40 to 50 lbs. of honey.

Scottish apiarians who have thus availed themselves of sending their hives to the moors and Heath-clad hills will find them, even after the appropriation of some well-filled supers, in splendid condition for wintering; and it may be hoped that having at last obtained, on the whole, one good honey season, it may be the harbinger of a series of prosperous years to follow.—J. LOWE, *Slateford House, Edinburgh.*

NOTES ABOUT BEES.

SURELY bees were never in a better state of health and spirits than they have been this October. It has not been necessary with me to feed more than one hive which I had plundered rather freely, and which had been disturbed by the union with it of the population of a stock of degenerate Italians, whose queen it was desirable to dispose of. At such times there is always some extra consumption of food; yet even here 5 lbs. of sugar was enough to make-up what was needed, because of the surprising quantity of Ivy blossom honey which all hives are storing as busily as in summer-time. I see cells on the outskirts of the combs that had been quite empty glistening with this honey, which seems to abound in unusual quantities. Of course breeding is going on largely, and pollen is taken in in fair quantities. The honey itself is simply unsuited for human food, but good enough evidently for bees; perhaps there is something of the nature of a cordial in its pungent acrid flavour, which may be specially useful to bees at this time of year.

My experience this year with long expanding bar-framed hives holding as many as sixteen frames has led me and others to think that little is left to be desired by the practical bee-keeper. Mine, I think, are too narrow and not deep enough. Large frames would answer better; but the principle is, I am persuaded, a good one. I have four such hives in operation, and although each began the year with little more than a pint of bees, they have in every case filled every comb first with brood, then with honey, and given me some good comb besides in supers. Two of them swarmed, one of the swarms being lost during my absence from home, but apparently with little diminution of the population. A good size of frame would be 14 inches clear width, and 9 inches in depth. In winter dummy frames at each end reduce the home nest to seven or eight combs. The ends should be filled with shavings or paper loosely crumpled up. There is practically no

limit to the length of these hives, which may be made to hold twenty frames in a good honey district, to which the bees can have access given over and above the brood nest from time to time as they need room. It is only necessary to shift the dummies to the right and left, for which reason they ought not to be fitted into a groove, but should be allowed to slip easily along the hive ledge. The frames should be covered over either with the quilt or narrow strips of wood a quarter of an inch thick, so as not to uncover more of the combs than is necessary for the purpose of access to any part of them at any particular time.—B. & W.

BRITISH BEE-KEEPERS' ASSOCIATION.

THE quarterly conversazione of this Association was held on the 27th ult., and fully maintained the character of these interesting and useful gatherings. The Rev. Stewart Walford having been called to the chair, Rev. E. Bartrum, the essayist of the evening, proceeded to read a paper upon the Stewarton hive, which was at once excellent in matter, structure, and expression. Having traced the history of the Stewarton from the octagon box of the middle of the seventeenth century to the form it has reached under the improving modifications of the "RENFREWSHIRE BEE-KEEPER," he proceeded to explain, by the assistance of a set of hives, the method of management, pointing out the elasticity of the Stewarton with the advantages it possessed in preventing the intrusion of the queen into the honey boxes, both by the use of slides wide of the centre, and the presence of a super with elongated or filled cells immediately above the proper scene of her activities. The good results arising from an external case in promoting ventilation and screening from wide fluctuations of temperature were pointed out, and the great control over swarming by eeking and giving space below when required by an additional body box was well explained. Mr. Bartrum recounted his fine results with Stewartons, which were in advance by much of those he obtained with ordinary bar-framers, and referred with evident satisfaction to the doings of the acknowledged Stewarton champion, the "RENFREWSHIRE BEE-KEEPER." He also expressed a strong opinion that the attention the hive required was less than that demanded by most, and that therefore the Stewarton was the hive for the busy man. The paper closed by some stirring lessons for humanity drawn from the thrift, the earnestness, and the perseverance of the wondrous bee.

The discussion was started by Mr. Cowan, who stated that after ten years' experience with the Stewarton he could merely regard it as an excellent hive, taking a sort of middle place between the skep and the bar-frame. He could not agree that the Stewarton was less troublesome than frame hives; on the contrary, he had found all manipulations with them to be slow. The advantage of eeking as preventing swarming was easily reached in ordinary moveable-comb hives by giving space in the centre of the brood nest when a disposition to swarm would be quite as thoroughly controlled. He thought the large quantity of honey that the Stewarton system required to be gathered before boxes could be removed a disadvantage. He stated that a crate of twenty-one sections would keep any stock busy if the sealed store was taken away as soon as complete, and that the honey would be the better for this prompt removal. Mr. Cowan then explained a plan he had employed this autumn to save trouble in obtaining sealed store for wintering stocks. He removed a queen and then fed the bees freely, keeping the hive artificially at a high temperature. Perfect slabs of comb, every cell sealed, were soon at command, and these were divided amongst other stocks as needed.

Mr. Cheshire pointed out that he had made every comb moveable in the Stewartons he used by adding frame sides but not bottoms to the outside bars, making these triangular in section. He said that a few years since it was common to so manage the frame hive that it was practically inelastic. Swarms large or small were alike put within, and but few dreamt of reducing the internal capacity under any circumstances, not even in winter. The Stewarton, on account of its expansibility, would have over frame hives, thus handled, no inconsiderable advantage; but the frame hive as we now find it in good apiaries can be adjusted with much greater nicety than the Stewarton, which must pass at once from one body box to two. He gave some account of the nature of the instinct which forbade swarming with an unfilled eke, and pointed out that frame hives gave much better opportunities for enlarging the brood nest in spring to promote breeding than did the Stewarton. He said that bees true to mathematics gave their brood nest a globular form, as this figure had the largest mass for its surface, and thus was most economical of heat and labour. When this form was interfered with every effort was made to restore it. Single Stewarton boxes would winter well, especially if surrounded by chaff and supplied with pea flour cake, the benefit of which could not be over-estimated. He related some good results in Stewartons from very small lots of bees, which he thought he could hardly have reached with any other form (a statement with which Mr. Cowan hardly agreed), and closed by saying in reference to uniting swarms that some carefully conducted French experiments had seemed to show that bees benefit by massing until about 12 lbs. is reached, but beyond this uniting results in loss.

The Rev. G. Raynor stated that although he had found greasing the slides with tallow at first an advantage, yet the bees soon removed it, and propolised as freely as upon clean wood. The Stewarton

of thirty years since he had not found a form that could be commended, but, as we now have it, it is greatly improved, and is really in part a frame hive. Notwithstanding this he found it awkward to manipulate, and often a necessary investigation would cause the painful crushing and destruction of many bees. He thought the screws and buttons nuisances that should be at once removed, and that the great height to which the hive sometimes reached was a discomfort to the bee-keeper and a danger to the stocks. He should never like to be wholly without Stewartons, yet the ordinary frame hives were those to which he looked for the main work of the apiary. Captain Campbell explained the history of the Stewarton he possessed and his early difficulties, and stated that he had made the same addition as Mr. Cheshire, and could now apply the extractor whenever required. The slide-sticking trouble he overcame by putting between the slide and bar a piece of sheet steel about 3 inches wide and prizing the two apart till the propolis separated with a crack. He found that the Stewarton could be left longer without attention than other forms, and so liked it as thoughts of the bees did not so much interfere with yachting trips. After Mr. Bartrum's reply, the usual votes of thanks terminated a very enjoyable and profitable evening.

HONEY AT THE DAIRY SHOW.

THE idea of associating the produce of the apiary with that of the dairy was, we believe, conceived by the earnest Secretary of the British Bee-keepers' Association, and it was done so well that milk and honey, long ago the emblems of fertility and abundance, are likely again, we should think, to appear in company. The hives were but few and not particularly remarkable, those taking the first prizes in Classes 94 and 95, both made by Mr. Blake, having little to recommend them except solidity and cheapness. They both contained by example the old (we had hoped obsolete) and inconvenient rack to take the frame ends. The exhibition of honey, however, was extremely fine in quality and finish, and being tastefully staged, made not only a novel but a most inviting addition to the general exhibition. The aggregate was greater than that collected at any previous time, amounting to no less than 3 tons. As late as July of last year we had to point to the beautiful flatness of the 1½ ton of American honey shown at Kilburn; but the English producer has risen to the occasion, for not only now do we find old adepts with their perfect combs, but new names are attached to exhibits which were not inferior to the very best American examples. Mr. J. T. Thorne in the best display had sixty-two sections of spotless comb, taking first, while Mr. Cowan came second, showing thirty-six sections carrying combs perfect in form and colour. Mr. Rusbridge exhibited some beautiful slabs, but as their weight was greater than that allowed in the schedule he was not admitted into the competition. No. 1102 was wanting in flatness through neglecting the separator. Quantity helped the Judges in this class, but in the next, limited to twelve sections, they must have been sorely tried. Here Mr. Cowan justly won, putting Mr. Rusbridge second, and Mr. Thorne third; Rev. H. Peel and Mr. S. Thorne being highly commended. Mr. Smith's boxes were exceedingly neat, while Mr. Hooker showed 1 lb. sections, which in such a competition with heavier metal could not win. Class 98.—Mr. Cowan surpassed all comers with combs that would delight a geometer, Mr. Brooks taking second with extremely pretty and well-got-up boxes. Class 99.—Supers of honey. Mr. Rusbridge won with a splendid set of combs 6½ lbs.; Mr. Cowan was second with a beautiful Stewarton daintily staged with an octagon glass cover edged with light blue paper. The extracted honey of Classes 100 and 101 was for the most part excellent, but one or two exhibits partook of that porter-like tone which speaks of aphid contamination. Such honey has no chance of winning. The clarity of almost all was remarkable, proving most unmistakeably the perfect freedom from contamination of the article as thrown out by the extractor.

The difficulty of wording a schedule with regard to wax lies in the fact that where foundation is used no exhibitor could declare that he showed only the product of his own bees. We fear that this difficulty has made it possible for foreign blocks of bought wax to come successfully into competition with cakes procured from combs either worked out or built in the apiary of the exhibitor, and classified by his own hands or those of his assistant. If this be true it is at least unfortunate.

OUR LETTER BOX.

Fowls for Profit (M. F. G.).—We should advise you to try two Dorking cockerels, six Dorking pullets, and six Brahma pullets. As the Dorkings lay white eggs and the Brahmas brown, they can easily be distinguished. For early and late broods set the Brahmas' eggs, the produce from which will be very strong and hardy and good table birds when young. From February to July set the pure Dorkings' eggs, which will produce chickens excellent to eat at almost any age.

Mixing Ducks (E. C. O.).—It is impossible to be sure of the produce of two breeds of Ducks, like Aylesburys and Buenos Ayres, kept on the same piece of water. We have this year tried it on two pools, one a very large one, and in both cases failed. There would be more chance of keeping them pure if the second breed were wild Ducks, strictly paired, or some of the very small Call Ducks or fancy Ducks.

Canary Songless (Idem).—No one can be sure without seeing your Canary what the cause of his ceasing to sing is. He may be old or weak in

lungs, or he may have moulted late and not yet recovered his song. We think the latter the more probable reason. Try a little stimulating food, such as sponge cake dipped in sherry, and have a little patience.

Ligurian v. English Bees (Comber, Co. Down).—We will reply to your letter by saying that "doctors differ" so much in regard to the merits of the one bee over the other that it is difficult to gauge those merits accurately. We have no others in our apiary but either pure or hybridised Italians. It is many years since we have introduced and used them, but with the exception that they are good-looking and the queens are wonderful egg-layers, we cannot say that we have found any marked superiority in the one breed over the other, or in the quantity of honey they gather. We have sometimes thought them earlier abroad and more active than the old English bees, but on the whole we cannot speak more positively on their merits. If others can speak better of them let them do so. Should you be tempted after this to try them let us know and we will help you further, but it is not a time of year to introduce them.

Preserving Syrup (Bertie).—The coldness of the atmosphere is probably the cause of your bees not taking the syrup presented to them. When the mercury of the thermometer falls below 50° bees can do little work either inside or outside their hives. If you were to warm the syrup and give it to your bees in a hot-house or warm room they would take it readily enough if they are in a healthy state. If you do not use it now, boil it well and keep it in a cool place. Closing the doors of your hives with perforated zinc will do no good, for bees do not fly about in cold weather. If the zinc were left on when they want to come out it would do harm. Contract the doors so that mice cannot enter the hives, and let the bees have liberty to come out when they like when snow is not on the ground.

Gold Fishes Dying (Mrs. Burt).—If the tank in which the fish was placed had been recently cemented the fresh cement would render the water injurious. We are unable to suggest any other cause for the loss of the fish.

REMARKS.

24th.—Fine, bright, cold day; cloudy evening; fog in town, but not here.
25th.—Fine, but not very much sunshine; rain after 9.30 P.M.
26th.—Thick fog in early morning; rain commenced at 8 A.M., continued the whole day.
27th.—Foggy morning; rain all the forenoon; fine, with a gleam of sunshine between 2 P.M. and 4.30 P.M.; heavy shower 5 P.M.; windy evening, and fair.
28th.—Stormy day with frequent showers; much wind in previous night.
29th.—Cold wet morning, clearing off at 11 A.M.; fine afterwards, with sunshine for a short time at noon; cloudy evening; starlight at 10 P.M.
30th.—Thick white frost in morning, very cold, but fine dry day with bright sunshine.
Temperature lower than last week, and rather below the average. Heavy gale in night between 27th and 28th.—G. J. SYMONS.

COVENT GARDEN MARKET.—NOVEMBER 3.

TRADE keeps very quiet. Large consignments of Apples from America and Canada have again reached us. Home-grown fruit is now beginning to fall off in supply, the bulk of the crop having changed hands.

TRANSPLANTING GOOSEBERRY BUSHES— GOOSEBERRY CATERPILLARS.

FOR the first time for several years we have some leaves remaining on the Gooseberry bushes at pruning time, and what, too, has lately been unusual, we have good ripe growths of considerable length to be shortened. We may, therefore, with confidence expect fruit of larger size and better quality; for although the Gooseberry is very accommodating, and never fails to produce abundance of fruit where the bullfinches are kept in check, it cannot bring that fruit to perfection without sufficient foliage. I suppose everybody is aware how insipid the fruit is—from a bush which has been denuded of its foliage during the growing season; but I suspect everybody does not bear in mind how much the crop will suffer in quality during the following year. It should be remembered that foliage is as necessary in summer as it is in spring, and that the processes of growing fruit buds and maturing the growths require the combined assistance of both leaf and root. I have had the most satisfactory results this season from young bushes which were shifted during the autumn of last year, and I can almost promise anyone immunity from the caterpillar during the coming season who will take up young bushes now, well wash their roots, and plant them 20 or 30 yards distant from ground which has been cropped this year with Gooseberries or Currants. It appears to me that the Gooseberry sawfly is not a great traveller, possibly it does not live long enough to travel far. I should like information on this point from entomologists, and, if it is not forthcoming I must find it for myself another season; but this much I know, that only a wall 10 or 12 feet high separated infested from clean bushes which had been shifted, and that the latter, some sixty or seventy in number, remained clean with the exception of two or three which unfortunately were slightly injured late in the autumn.

A similar experiment to this has been tried several times, and always with the same success. I therefore advise those who may be troubled with this pest to frequently make young plantations as distant as possible from the old, and where the space is limited to burn or remove the soil from around the roots of the old bushes when destroying them. I made a new plantation in the end of September, and have destroyed all old bushes except those which are on a border permanently covered with wire netting, of which more anon. It will not be too late to shift bushes any time before the middle of next

month, but the sooner they are planted the better. More of Warrington is grown here than of any other variety, as it keeps the best; and although it is a late Gooseberry I have not yet found any other so good in flavour when cooked in a green state. Many varieties are more profitable to grow for market, but anyone who likes green Gooseberry tart should test other varieties with this, and not be satisfied with an inferior one. Red Champagne is the best dessert Gooseberry I know, but it will not keep with me after the middle of September. Early Sulphur is the best early.

As the Gooseberry house, or rather the border, is permanently covered with wire netting, I have to adopt a different practice, and that, too, I am happy to say, has been successful this year. For two seasons previously a man and a boy have spent a good part of their time in this enclosure picking off the caterpillars, but the caterpillars won the day, and by the end of August there was scarcely a leaf to be seen. This season they bid fair to become more troublesome than ever, and, indeed, in this neighbourhood generally they were so. Most of the cottagers have given up attempting to grow Gooseberries, and acknowledge themselves defeated by bullfinches and caterpillars, but a few have tried to struggle on, and one old man who is past ordinary work tried his best to keep two bushes clean in his own garden, but the caterpillars were too much for him. Hellebore powder, I observe, is strongly recommended by some of your correspondents, but I will not run the risk of poisoning my employers, who eat Gooseberries very freely, preferring them to all other fruits after the Strawberries are done; and my own taste agrees with theirs, for I do not consider a Peach or a bunch of Grapes in summer fit to be compared with a handful of good ripe Gooseberries. But this is merely a matter of taste, and we must grow all kinds for visitors if not for residents.

The only safe and effectual remedy tried for caterpillars inside the Gooseberry house was fir-trec oil, and that was applied four times during the season, drenching the bushes all over by means of a syringe with a bent nozzle, at the rate of half a pint of the oil to three gallons of water. It is rather expensive to use in so large a way, but I do not expect to have so much trouble again, and I am in hopes of getting rid of the enemy altogether. One dressing was given after the Gooseberries were ripe, and that did not injure them, although applied during sunshine, the taste passing off in two or three days; but some Currants in the same enclosure were injured by using it on them after they were ripe, though it did not harm them in the earlier stages.

I find that different samples of water make a very great difference to the efficacy of this insect-killer; that which is soft and has been exposed a long time to the air being the best, while hard water is almost useless. As a rule, I think the whiter the water turns when the oil is put to it, the more efficacious it is likely to be.

I have previously said that we have two kinds of sawfly which infest our Gooseberries, totally distinct but equally destructive; now, as if that were not enough, we have this season been troubled with the larvæ of another one devouring the leaves of our Tea Roses. I daresay all these difficulties and troubles with which we have to contend are good for us, and prevent us giving way to lazy habits.

I refer to this subject now, as although there are no caterpillars to destroy, there are numbers of Gooseberry bushes that

may be removed with advantage, and the present is the time for transplanting them.—WILLIAM TAYLOR.

SARRACENIAS.

It has often seemed strange to me that Sarracenias are not more popular. Perhaps some may say that they are difficult to manage, others again may say that they are not sufficiently showy, but to these excuses I answer that they are both showy and easily cultivated. Some of the species have been introduced to our gardens upwards of a hundred years, and yet how seldom do we meet with them, except in botanic gardens and a few establishments where large collections of plants are grown. A few years ago there were only about half a dozen species in cultivation, but now in addition some fine hybrids have been obtained by Messrs. Veitch & Sons of Chelsea. The great outcry at the present day is for new plants and Orchids; but if some of the new plants that are sent out annually were nearly as attractive as some of the Sarracenias we should not have room to complain. I have been a close observer at the great metropolitan exhibitions for this last few years, and have come to the conclusion that few new plants of really sterling merit have been sent out. If Sarracenias were an introduction of the present times instead of the past I am sure they would find favour with many plant-cultivators, for when well grown they are really ornamental.

Perhaps a few words on their cultivation will not be out of place to some of the readers of your Journal who may wish to give them a trial. I find that Sarracenias are very accommodating, not at all particular as to the house in which they grow. I grow mine through the summer in a light airy greenhouse well ventilated top and bottom, and in winter I place them in the coolest end of the stove. This is merely for my own convenience, for it is not absolutely necessary that they should be in heat in winter, as I have known some growers allow their plants to be exposed to frost for a considerable time. I have tried two or three composts for them, but what they like best is good fibry peat, chopped sphagnum, broken charcoal or potsherds, and plenty of silver sand. Some prefer potting their plants in autumn, others in spring. I prefer potting in spring before they make their spring pitchers. The pots should be washed and be filled about a quarter full with good drainage, or if large a little more drainage will be all the better; over this place a thin layer of moss, and then the potting proceeds. The crown or rhizome should be slightly elevated above the level of the pot, the plants being potted rather firmly, leaving sufficient space at the top for a good top-dressing of green sphagnum. After the plants have become sufficiently large pans are the most suitable to grow them in. In their native habitat Sarracenias are found growing in boggy or marshy ground, consequently they require a good amount of water both in summer and winter; in fact, they should never be allowed to become dry. The plants when growing should occupy a position near the glass and be fully exposed to the sun, for if shaded the colouring of the pitchers is not nearly so bright. It is very necessary to guard against the flies, for these intruders are very fond of the secretion produced by the pitchers when in a young state. If the flies are allowed to become entrapped in the pitchers in any quantity decomposition soon takes place, and causes the base of the pitcher to decay. I find that placing a small piece of cotton wool in the top of each pitcher, sufficiently far down to be unobserved, answers the purpose admirably.

The following are amongst the most useful and showy forms:—

S. Drummondii.—This is one of the best species grown. The pitchers are quite erect, and from 1½ to 2 feet high, of a bright green colour, the upper part being beautifully variegated with red, green, and white.

S. Drummondii alba.—Another handsome form, differing very little from the typical species, except in the colouring at the top of the pitchers; instead of being variegated, as in the last-named, it is nearly pure white.

S. Drummondii rubra.—This is very handsome, the pitchers being beautifully variegated with crimson.

S. flava and *vars. ornata* and *pieta*.—These are all attractive forms, especially *S. flava ornata*, which produces pitchers of an enormous size, and remarkable for its bold and clear venation, which is of a dark purplish red. The flowers are large and handsome.

S. atrovirginica.—A strikingly beautiful variety. The pitchers are long and narrow, and of a greenish colour; the lid is heart-shaped, the lower part green, and the upper part blood red with a satiny hue.

S. purpurea.—A good old species, quite hardy, and producing

cup-shaped pitchers about 6 or 8 inches long, and, as the name implies, are of a bright purple colour.

S. variolaris.—This is well worth growing, and should be in every collection. The pitchers are peculiarly hooded, growing between 1 and 2 feet long, and beautifully mottled.

S. psittacina.—Quite distinct from any of the former in habit of growth. Instead of growing erect it produces its pitchers horizontally or spreading; the pitchers are light green with crimson veining, and are curiously hooked at the end, much resembling a parrot's bill.

S. rubra.—Also well worth growing if only for its flowers, which are blood red and deliciously fragrant like Violets. The pitchers in this species are not so showy as in many of the others, from a horticultural point of view, but where a collection is grown it well deserves a place.

S. Chelsoni.—A beautiful hybrid of Messrs. Veitch's raising. It is much in the way of *S. purpurea*, which is one of the parents. The pitchers grow erect, of great substance, and very wide at the mouth, the colour being a bright red.—W. K.

OXFORD BOTANIC GARDENS.—No. 1.

FEW strangers visit the city of Oxford without carrying away many pleasant memories of its antiquities, curiosities, and attractions generally. These are, of course, differently viewed and appreciated according to the particular taste of the individual, but to all they are interesting, varying only in degree. The historian, the antiquarian, the architect, the student of literature, and the casual visitor who merely wishes to see all that is noteworthy or admirable, find abundance that is instructive and entertaining. The numerous colleges, all invested with interest of no ordinary degree; the stirring history associated with so many spots; the literary wealth and curiosities of the Bodleian Library, and the contents of the various museums, especially Tradescant's collection, provide attractions which are excelled in few English cities of the same extent. Much has been and could still be written in praise of Oxford generally, but the above passing reference will suffice at present. I intend confining my remarks to what will probably most concern the readers of the Journal—namely, the Botanic Garden.

In that rare but useful work, Johnson's "History of English Gardening," occurs a passage which, as it directly bears upon our subject, may not be inappropriately introduced. After commenting upon the fact that previous to the reign of Queen Elizabeth horticulture had been regarded as little more than a mechanical art, the author continues as follows:—"Botany previous to this period was almost unknown as a science, and it must be acknowledged that botany is a chief part of the only foundation upon which an enlightened practice of horticulture can be raised. In this reign England was enriched with the first regular establishment for the scientific cultivation of plants in the Physic Garden of Gerard (1567)." More than half a century after that—namely, in 1632, the Oxford Botanic Garden was founded; and though it cannot claim to be the first established, it is the oldest botanic garden at present existing in Great Britain, nearly two centuries and a half having elapsed since its foundation. A brief glance at the history of the garden during that period may not be devoid of interest, for many men of considerable eminence have been connected with it either in the capacity of professor or curator. The founder was Henry Danvers, Earl of Danby, who enclosed five acres of land on the banks of the Cherwell, near St. Mary Magdalen's College. He had several glass houses erected for plants from tropical and temperate regions, a residence also being provided for the curator. In his will the Earl of Danby bequeathed a rectory in Yorkshire, the funds arising from which he intended to be applied to the maintenance of the garden in suitable condition, and to provide a salary for a professor, but the latter idea was not carried out for some years, as the income derived from the estate proved insufficient for the purpose. The first curator selected was, I believe, John Tradescant, but he did not accept the appointment, which was consequently obtained by a German named Jacob Bobart. This man appears to have assiduously endeavoured to increase the number of distinct plants grown in the garden, and if the catalogue he published in 1648 is reliable he must have succeeded very creditably. Sixteen hundred species or supposed species were cultivated at that time—no inconsiderable collection for the middle of the seventeenth century. Ten years subsequently another edition of this work was issued under the joint editorship of the Bobarts father and son, Dr. Stephens, and Mr. William Browne. A copy of this I have now before me, and it is remarkable chiefly for the fact that many synonyms are given with references to Gerard's and Parkinson's works where the plants named are described; the common names are

subjoined to the Latin, and there is also an alphabetical list of English names.

Dr. Robert Morrison was appointed professor in 1669. He was physician to Charles II., and is chiefly noted for his "*Hortus Bloisensis*," and a history of the plants at Oxford, which he commenced but did not live to complete. In 1679 the elder Jacob Bobart died, having reached the advanced age of 81, and from his time until the present century we have few records of the succeeding curators. Jacob Bobart, son of the last named, was appointed professor on the death of Dr. Morrison, but little is known respecting his works, except that he published a continuation of Morrison's history already referred to. Of Mr. Edwin Sandys and Mr. Gilbert Trowe who succeeded him it is not necessary to give any details; but the garden was greatly improved about that time by the liberality of the eminent Dr. William Sherard, a friend of Ray and Dillenius. He contributed large sums of money during his life and by will towards the improvement of this garden and the support of a professor. He also obtained the appointment of Dillenius as professor in 1728. The latter is so well known that any particulars respecting him would be needless, and the same may be said of Dr. Humphrey Sibthorp and Dr. John Sibthorp, who followed in the capacity of professor. The "*Flora Græca*" of the last named is justly famed. Dr. George Williams succeeded and fully maintained the character of the garden, the lowest parts being raised to avoid the inconvenience of the occasional floods to which they had been subject. Dr. Charles Daubeny was appointed to the chair in 1834. Many and important improvements were effected during his life, and are still admirably continued under the direction of the eminent and respected Professor Lawson who now holds the chair.

In connection with the history of the garden it only remains to refer to the Baxters, who have so admirably performed the duties of curators for the past seventy years. The present condition of the garden is a sufficient indication of the care and intelligence with which it is conducted; and perhaps a greater compliment could not be paid to Mr. W. H. Baxter, the present curator, than by stating that he well continues the creditable management his father exercised before him.—L. C.

TRAINING ESPALIER FRUIT TREES.

WHAT should be the proper or best form for a hedge or fence? A practical common-sense labourer would answer the above question by saying "Hog-maned or tapering upwards." Well, if that is the best form for a hedge, why should it not be the best for espalier fruit trees? But what as a rule do we see? Why, espalier fruit trees bare of foliage at the bottom, and the top tier of branches overhanging the lower. This cannot be the proper method of growing espaliers. Why not, as in the case of a hedge or fence, allow the lower branches to extend their shoots so as to encourage the formation of wood, and thus give vigour to the base of the trees? I believe their productiveness would increase on account of the increase of healthy spurs at the base of the tree.

I have been encouraging for three years the increase of the basal growths on both Apples and Pears, and can see a positive improvement in the health, vigour, and form of the trees so treated. Last season was not a favourable one for fruit crops, but I anticipate with anything like a favourable season to have better crops from the espaliers so treated than have been realised for several years. No doubt my opinion may be thought crotchety, but I maintain that without plenty of good healthy foliage and well-ripened wood it is impossible to insure good crops of fruit, and the spurs on the lower branches of the trees cannot be so well ripened as they should be if they are shaded by the upper branches. I am also of opinion that frequently for the sake of neatness fruit trees are the victims of the gardener's knife, which is as baneful in its effects as the gardener's foot.—J. GADD.

GOLD AND SILVER FERNS.

AMONG the numerous handsome Ferns which now have a place in our houses, few are more generally admired than the Gold and Silver Ferns, as the species and varieties of *Gymnogramma* are appropriately designated. Having elegantly divided fronds, usually dark green on the upper surface and plentifully sprinkled with a yellow or whitish powder beneath, being easily and quickly grown and readily propagated by means of spores, the plants possess ample merits to entitle them to popularity. It is therefore scarcely necessary to say much in their favour by way of inducing their more extensive cultivation, for there are few lovers of Ferns who do not include in the smallest collections some

specimens of these attractive plants. However, as there may be some who are unaware how easy it is to obtain such Ferns in good condition, a few remarks upon the treatment that I have found to suit them will possibly be of some utility.

Gymnogrammas are chiefly natives of tropical regions, the forms in cultivation being from the West Indian Islands and South America. One of their most important requirements is therefore a stove temperature, or such as is provided for tropical Ferns where a separate structure is devoted to them. During winter this should not be allowed to fall below 50° Fahrenheit, a range of 10° upwards being permitted; but too high a temperature at that time of year is inadvisable, as it tends to cause a weakened immature growth. In the summer the maximum should be about 80°. They need more exposure to light than many Ferns, the sunny side of a fernery or a slightly shaded position in an ordinary stove suiting them admirably. Abundance of water is required whilst they are growing and during hot weather, but as they are most impatient of any approach to stagnation the composition of the soil and the drainage must be carefully attended to. A compost of fibrous peat, light loam, abundance of sand with some small pieces of charcoal well incorporated, constitute a good soil, encouraging vigorous and healthy growth. The drainage should be regulated according to the size of the pot, placing the large potsherds at the bottom of the pot concave side downwards, filling up to the necessary height with small pieces and covering with a layer of moss. Upon this some of the compost described above can be placed and the plant potted rather firmly, allowing a moderate space from the rim of the pot to the soil to facilitate the supply of water. In some of the varieties the fronds are long and heavy with rather weak stems, necessitating the employment of a few light thin stakes, to which the fronds must be secured, or they are liable to be broken. Another point that needs attention is to avoid wetting the fronds, as the delicate silver or gold farina is quickly washed off and the chief beauty of the plants destroyed. This is one inconvenience that attends the introduction of *Gymnogrammas* into a plant stove, as unless they can be allotted a position where they will not suffer from the frequent syringing required for the other plants their appearance is never very satisfactory.

Gold and Silver Ferns are most readily increased by spores, as these germinate in a few weeks; in fact, they are some of the quickest to germinate of the whole family of Ferns. The best mode of effecting this increase is to remove the fertile fronds from the plant before the spores are fully mature, placing them in a dry warm house until they are ripe. Shallow pots or pans should be prepared by thorough drainage, upon which there should be placed a layer of sphagnum, filling up with very finely sifted loam and sand; and if the former has been baked it is better, though so much care is not needed with these as with more delicate or longer-germinating Ferns. It is one of the peculiarities of the genus that the young plants produced in this way are extremely variable both in the form of the fronds and the colour of the meal or farina, and it is owing to this circumstance that many forms, varieties, and probable hybrids have been obtained.

The following will be found a good selection:—*Gold*: *G. chrysophylla*, *G. Lauchiana*, *G. L'Herminieri*, *G. Martensii*, *G. decomposita*, and *G. sulphurea*. *Silver*: *G. Calomelanos*, *G. tartarica*, *G. peruviana* and var. *argyrophylla*, *G. pulchella*, and *G. Peareei*.—C. S.

PLANTING POTATOES IN THE AUTUMN— PREPARING SEED TUBERS.

A FEW weeks since you stated that you would insert in the Journal any communications on planting Potatoes in the autumn. About twenty-six years ago I commenced planting in the autumn, and continued it for several seasons. They were chiefly late Potatoes. Some were planted on a heavy loam, where the slugs devoured many of the sets. The crop produced was not nearly so heavy as those planted in the spring. The same varieties were planted on a sandy loam, where the soil runs closer together; consequently the slugs did not injure the sets so much as the others. They were planted about 7 inches deep. The growth did not appear as soon as of those planted in spring; the produce was more uniform in size, but there were as many diseased tubers, and I think a few more, as they were not ready for digging so soon as the crop from the spring-planted tubers, which were not planted so deep and had more heat from the sun. I found that on the autumn-planted ground the weeds commenced growing a long time before the Potatoes, which made it difficult to keep them clean, as it was not safe to use the hoe; the heavy soil became very hard during dry weather.

I have occasionally planted a few early varieties in the autumn

on a south border, but they come up earlier than those planted in spring, and have to be covered with soil or other material to keep the frost from them, while they are not ready for digging a day earlier.

I can fully endorse all that Mr. Luckhurst says about spreading the seed tubers out thinly to be exposed to the light and air. They cannot be kept too cold provided they are safe from frost. I am surprised that so very few practise this method of keeping their seed Potatoes. I have all my early and second early seed tubers placed in propagating boxes. The kidneys are put on their ends with the eyes uppermost. It is surprising to see how many can be stored in a small space. It may appear too much labour to place them so carefully; but a man will place many bushels in the boxes in a day, and sometimes we have wet days in the autumn. The tubers are now showing their stout shoots, which will never be broken off. They will not require to be handled until they are carried in the boxes to the ground where they will be planted. The tubers do not produce growths so thick as my finger, but that is perhaps owing to my planting them earlier than Mr. Luckhurst does, as I begin by the middle of March, and have them all planted as quickly as possible if the soil is sufficiently dry to work upon.

In the autumn I ridge up all the Potato ground, the ridges being the width of the space between the intended rows. If any manure is required on the ground it is dug in at the time of ridging. At the planting time the ground between the ridges is levelled, leaving sufficient soil on the top of the ridge to cover the sets the required depth. I never in any case earth up early Potatoes, as it only places them farther away from the heat of the sun, and they are not ripe so early. I keep the hoe frequently at work until the haulm spreads, so as to prevent the growth of weeds, and the loose surface prevents evaporation of moisture from the roots. With regard to late Potatoes, if they are bursting the ground open I then fill up the cracks to prevent the tubers becoming green.—D. WALKER, *Gardener to B. H. Collins, Esq.*

WINTERING FUCHSIAS.

SINCE Fuchsias have taken such a prominent position among bedding plants, keeping them in winter has become an important matter. Left in the ground as "W. J. M." advises, the roots and crowns remain alive, but stems and branches are lost. I well remember one spring seeing a considerable number of old plants exhumed from a heap of leaves in which they had passed the winter with roots and branches all alive; but where pits or frames can be had it is better to plunge them therein and protect them from frost. I had six beautiful beds of Fuchsias this year, and the plants now fill two old three-lighted wooden frames, in which they were crowded as closely together as possible when lifted from the beds. A bank of soil is made around the outside to the top of each frame; this, with some litter thrown over the lights when necessary, served admirably to exclude frost during the last two severe winters. Inside the soil is excavated deep enough to admit the tallest plants: care has, however, to be taken to do this on a position sufficiently elevated to be safe from flooding, which would prove fatal to the plants. By this rough and ready means I have in spring a large batch of most valuable bedding plants, which are planted out early and quickly become ornamental, retaining their freshness and beauty till the first severe frost of autumn warns us to take them into winter quarters once more. Not only do I value beds of mixed Fuchsias for their beauty, but also for the admirable manner in which the monotony of the too common flat surfaces of ordinary beds are relieved by them.—EDWARD LUCKHURST.

A WEEK IN YORKSHIRE.—No. 4.

FERNIEHURST.

AFTER visiting Mr. Holden's remarkable garden at Oakworth, an agreeable hour was spent at Ferniehurst, the pleasantly situated residence of Edward Salt, Esq. Mr. Salt's mansion is situated on a woody eminence, overlooking the town of Shipley and that monument of the success and liberality of the late Sir Titus Salt, Bart.—Saltaire. The approach to Ferniehurst is by walks and drives along the side of the hills, arranged so as to diminish the gradients and make the ascent as easy as possible. There is a great deal of the grandeur of Nature flanking these drives, abrupt banks and deep dells, with an undergrowth of Ferns and a wealth of forest trees. There are also some touches of art, appropriately gentle, for evergreens have been planted to give warmth in winter, and as the house is approached we pass through an avenue of Rhododendrons recently formed—fine shrubs thriving well of excellent varieties, as the names attached to them indicate. The

walks and drives are highly suitable for the undulated nature of the ground. They are of asphalt, but very different from asphalt walks as ordinarily made and understood. When the tar was hot the surface was closely covered with finely broken granite and well rolled: no tar is apparent, and the granite though quite level affords good foothold for man and horse. Anything more suitable for hilly ground than this mode of making roads and walks cannot well be imagined. They are firm, dry, level, and agreeable in appearance, comfortable to walk upon, and free from weeds. A striking feature of the place is the grass and the asphalt tennis grounds situated in a romantic dell—the grass for dry weather, and the asphalt for use when the lawn is damp. The asphalt is enclosed with wire fencing 12 feet high, and the surroundings are very beautiful—massive rocks and Ferns with a well-arranged rustic bridge used as a walk from which the lawn tennis ground is seen with great advantage.

The gardens are not extensive, but the results of attentive care and good culture are apparent throughout. Orchids are admirably grown at Ferniehurst, but the collection is not so extensive as formerly, or at least the specimens are not so large. No plants could be cleaner nor in better health than the Cattleyas, Dendrobiums, &c., in the principal house, while in the cool house the plants were in the same satisfactory condition. Among the Masdevallias were excellent examples of *M. bella*, *M. Davisi*, a foot across; *M. towarensis*, growing vigorously; while several forms of *M. Harryana* and *M. Veitchiana* were very fine. *Epidendrum vitellinum majus* was healthy and brilliant, and three plants of *Oncidium zebrinum* had a spike each 12 feet long, bearing hundreds of richly marked flowers. *Odontoglossums* were numerous. Of *O. Uro-Skinneri* there was a grand variety flowering with glowing crimson sepals and a rosy purple lip; a finer variety is seldom seen. *O. macranthum* contributed to the beauty of the house by its large and richly coloured flowers. *O. Alexandræ*, *O. Pescatorei*, and *O. cirrhosum* were numerous and excellent, but as regards variety and condition, the pseudo-bulbs being of unusual size, and of that warm coppery brown colour indicative of good health and maturity of growth; while *Mesospididium vulcanicum* attracted attention by its richly coloured flowers. *Coelogyne cristata* is admirably grown, some of the plants exceeding a yard in diameter.

In other houses *Lapagerias* were growing in wild luxuriance. These plants are evidently at home at Ferniehurst, and Mr. Culley appears able to "do anything" with them. Planted out and in pots they grow alike freely, and they are increased both by layers and cuttings with the greatest readiness. A spongy turfy soil, with charcoal and abundance of water, appear the chief means employed of growing them so well. The young shoots breaking through the soil resembled heads of Asparagus, and were protected from slugs by half-circular earthenware troughs containing water, two of which placed together encircle a shoot, and they can be removed at any time. Overhead the flowers were numerous and grand. A fine plant of *L. alba* was sent from Ferniehurst to Milner Field, Mr. Titus Salt's residence, where the splendid flowers were produced that Mr. Anderson, the gardener, sent to South Kensington on August the 10th. One of Mr. Titus Salt's plants, I was credibly informed, covers the roof of a house about 40 feet long, and as many as four thousand flowers were expanded at one time this season. I regret I was unable to see this splendid sight, and what is believed to be the best plant of the white *Lapageria* in the kingdom. *Eucharis* and *Pancratiums* are admirably grown at Ferniehurst—huge plants in vigorous health. Equally fine are several specimens of *Anthurium Scherzerianum*, which produce between two and three hundred spathes each. Tuberous *Begonias* were extremely large and fine; the variety Queen of the Whites being found particularly useful, and some seedlings of it have proved as pure white as the parent. Small pots for the size of the plants and abundant supplies of water contribute to such good results.

In a small grotto-like fernery were some remarkable examples of *Lilium auratum*, the dwarfest plants with the largest flowers I have ever seen, and I have seen many thousands. The bulbs were imported last year and grown in very small ornamental glazed Japanese pots. The effect of these *Liliums* associated with the Ferns was excellent.

The Peach house is worthy of notice alike for its construction and the admirable condition of the trees. It is a span-roofed structure, and instead of the trees being planted close to the sides of the house they are planted 3 or 4 feet from it, and room is afforded for a flat stage close to the glass, and where Tomatoes and plants can be well grown, as they receive abundance of light. There is room also for a narrow path for attending to the plants. The house is lofty, and the trees are standards; they bear fruit of the first size and quality, and no red spider. In this house

some pans 2 feet in diameter filled with *Tritonia aurea* were remarkably fine; the bulbs appeared to have been packed together as closely as possible, and the effect of the rich masses of flowers was extremely good. I never before saw *Tritonias* nearly so effective.

Narrow pits are devoted to the growth of Figs and Melons—Figs on one side and Melons on the other. Negro Largo Fig was remarkably fine. Another pit contained Cucumbers on one side and Tomatoes on the other, while others were accommodating Vegetable Marrows and Dwarf Kidney Beans, which in this cold district have to be grown under glass. There are also some large vineries, and the crops of Grapes were very heavy, it being necessary to obtain as many bunches as possible for the requirements of the family. Mr. Culley is unquestionably a skilled gardener and industrious, or the plants, fruit, and gardens generally could not be maintained in such good condition.—A RAMBLER.

REMOVING AND REPLANTING OLD VINES.

IN order to dispel all anxiety respecting removing old Vines that are not succeeding so well as may be desired, I will relate the success of one that was removed under the most disadvantageous circumstances. A large estate having been sold for building upon, the workmen were engaged in taking down a vinery, in which the Vines had a very fair crop of Grapes about the size of Peas. The stems were severed about 3 feet from the ground, and the sap ran out in such profusion that the soil appeared as if water had been poured upon it. One of the men picked up a Vine with about a foot of thick root and a few fibres; I took this and planted it, for experiment, in one of my plant houses, without any preparation of border, the soil being light on gravel. The stem started into growth and made several good shoots the same season. The following year it grew vigorously; the third, it bore a fair crop of Grapes; and the fourth it had nearly filled the house, and produced over five hundred bunches. It continued to grow very freely, and produced a full crop every year. The house was 30 feet long—much too small for it, and I was very much inclined to lead it into an adjoining house. The variety was unnamed, but was a good and useful one. The bunches were of moderate size, berries roundish, rich amber colour when ripe, and possessed a rich, sweet, musky flavour.—R. C.

FANCY PANSIES.—No. 1.

THESE once-despised flowers have so rapidly increased in public favour as to now require no apologist. Their beauty and variety, their free blooming and rapid growth, their hardiness and easy culture, have been the passports that have carried them to a high place in the estimation of all who have given them a tithe of the attention they deserve. Florists of the good old school have hesitated and been lost. Four or five years ago judges, whose eyes and minds were filled with Roses and other more pretentious and fashionable flowers, were wont to pass by boxes of beautiful but unorthodox Pansies with the contemptuous remark, "A mongrel lot!" or with the singularly inapplicable designation, "Belgians!" Yet everyone liked, and likes, the flower, but their special attention has to be in a measure forced before they will take the trouble to minutely examine them. I have a friend who is a rosarian and orchidist; he will talk for a month about his favourites, do anything for them—get up in the middle of the night to make sure that he has latched the Orchid-house door, or protected from imminent rain a light Rose he intends showing on the morrow. Why, I have actually kept watch and ward with him through a short summer's night to protect the queen of flowers from the molestation of midnight marauders who were a good bloom or two short, or who were wishful of a dark Rose or a light to give variety to their box. But no foster-parent is he of the Pansy. Any that are given to him he plants in his stiff soil, rank with Rose food, and then leaves them to their fate—a hapless one. Yet he is enthusiastic in his admiration of them, and is no mean judge of their true merits. Perhaps this seeming indifference is a wise disposition of power. The best results follow an intelligent specialist—he aims at perfection, and generally succeeds to a certain extent.

That fancy Pansies have a bright future is as certain as that show Pansies have had a glorious past. "Your fancy Pansies are really magnificent," was the involuntary admission of Mr. Rabone, the skilful custodian of Alton Towers, "the fairy land of Staffordshire," when he was acting as Judge at the Stone Show in July last. The remark applied to a display of thirty-six varieties, staged for a special prize, for even there there is no open class for Pansies. However, they shared honours with the

new Rose Mrs. T. Jowitt, which is a Staffordshire Rose, by the way, having been raised at Newcastle, and this tribute to their beauty and variety from one who revels in all that is good and orthodox is borne out by the increasing demand. In a conversation a few weeks ago with Mr. W. M. Welsh, one of the firm of Messrs. Dicksons & Co. of Edinburgh, who have for many years had a well-deserved fame for Pansies and Violas, he said the demand in Scotland was three times as great for fancies as for shows; and I have good reason for knowing that his experience tallies with that of Messrs. Downie & Laird, and of Mr. Paul of Paisley, and these are giants of the Pansy world, and raisers of a very large majority of the really good varieties now in cultivation. "Depend upon it," wrote the latter about twelve months ago, "fancy Pansies are the Pansies of the future, not only for exhibition purposes but for general bedding," and I believe he is right. Stand by the boxes at a show and listen to the remarks of the visitors. It will be found that those which attract most attention are the fancy varieties, with their crimson and black, amaranth and primrose, scarlet and white, chocolate and yellow, cardinal and straw, indigo and magenta, mulberry and fawn, pink and lemon, lilac and orange, and a hundred other combinations of charming hues. This admiration, of course, is reflected in the demand, and consequently nurserymen propagate extensively of those most marketable, and sparingly of those for which there is but little sale. To be sold out of fancies and to have a large stock of shows is a state of affairs decidedly uncommercial, and will be speedily remedied by many of the show varieties being allowed to go out of cultivation. I was not a little delighted, about three months ago, when Mr. Mawley of the National Rose Society paid me the honour of a visit, that he carried away to his southern home a few fancies in preference to shows. But it is always so now. "With the exception of one or two really good dark selfs don't send me any of the old sorts," may be accepted as a fairly accurate representation of the radical change that has taken place.

I disclaim any idea of disparaging show varieties; I love them much, but the fancies more. The former have seen their day for the present, and the latter are well to the front. May they occupy their present position as long and as worthily as their predecessors.—M. H. MILLER, *Leek*.

NOTES ON BIRDS.

It will not require a very "learned" contributor to the Journal to answer the questions of "A. M. B." on page 389 as to the colour of the bill of the blackbird. The colour varies according to the age of the bird and also in the sexes, the hen never attaining the brilliant golden hue of the bill—so far as I have observed—but what is best described by the "orange tawny bill." The bill of the male bird varies according to its age until about twelve months old. When the bird is fully fledged its bill is a dark shade inclining to black, but becomes blacker until about six months old, when it is gradually streaked and mottled with orange, becoming by degrees a fine golden yellow in the winter. I was interested to-day (November 1st) in watching no less than five male blackbirds (not one of which had a yellow bill, although the old birds about have) under one Pear tree in my orchard turning over manure which had been applied a short time ago as a top-dressing, and on driving them away and examining the manure I found it contained an immense quantity of grubs or maggots, which the birds were feasting upon.

In the interesting communication of "A SURREY PHYSICIAN," page 398, I notice he remarks the swallows did not leave until the 21st October. I referred to my diary of dates of arrival and departure of the birds of passage, and find the swallows finally left here on the 15th of October, and house martins on October 16th. The latter birds have been unusually scarce with me this year, and in other places I have noticed the great decrease. On the front of one house I counted thirty-three nests, and this year there were only five. Last year I had just a dozen pairs round these premises, this year only three pairs. This is very strange, as there must have been nearly one hundred young reared last season. It is a pity people will not give themselves a little trouble to fix up a piece of board about a foot square under the nest to prevent the dung from a martin's nest becoming a nuisance, from which cause thousands of these useful and innocent birds are destroyed by having their nests knocked down by thoughtless people, instead of using every means to encourage and protect them. I could not help noticing one case in particular at Stratford-on-Avon when visiting the poultry and dog show on the 12th of October. A late brood of martins were still in their nest, which attracted my attention about opposite Shakspeare's birth-place, and turning to look I observed them directly over a bust

of the bard, who had been subjected to a continual shower of digested insects until he was hardly recognisable; whereas, a piece of board as above described would have prevented such shameful treatment.

Bullfinches are unusually plentiful this autumn; so, gardeners, look out for them now! And if endowed with a little patience, catch them instead of wasting powder and shot and spoiling your fruit trees in the spring when they attack the buds. Redwings and fieldfares are here in large flocks earlier than usual, but they find the hedges very short of provisions so far as haws are concerned, not one to be seen in a ten-mile walk, or even a berry on the Holly trees, for food for birds or Christmas decorations. The haws are not ripe, and so the birds have to betake themselves to pastures and pick up such food as they generally have to put up with after clearing off the berries.—J. HAM, *The Wren's Nest, Ashwood Bank, Worcestershire.*

NERIUM OLEANDER ELEGANS.

THE following few additional particulars in reference to this beautiful flowering plant (*vide* page 388) may have an interest for some readers, which I take by permission from a letter just received from the respected Curator of the Trinity College Botanic Gardens, Dublin, Mr. F. W. Burbidge. "When I paid my first visit to Paris some ten years ago my eyes were opened as to the capabilities of the Oleander. In the Halles Centrales I saw them in 5-inch pots, such as Pelargoniums are grown for Covent Garden Market, quite as dwarf and floriferous. Then there were so many shades of colour—white, blush, pink, and numberless shades of rose until a fiery crimson was reached; while the salmon and buff shades were exquisite, single as well as double. Outside the cafés and restaurants, particularly in the Champs Elysses, Rue Rivoli, &c., were large bushes of the old type, bearing gorgeous masses of rosy flowers. I came home with the impression that nowhere in the world could the Oleander be more beautiful than at Paris. Later, however, I saw them in Egypt with literally more flowers than leaves, while their fragrance rivalled that of the Roses. How they seemed to love the dry air and the blazing sun! At Kantarah, one of the Suez Canal stations, about thirty miles from Port Said, they perfume the whole place, and with big Arundos (Reeds) and fresh green Poplars make a refreshing oasis in a sea of dull red sand. I wonder, and have long wondered, why our florists and nursery gardeners do not grow them in small pots in the open sunshine. I hope shortly to put in practice an old resolve of mine, to see what may be done with the Oleander in small pots for autumn decoration when such flowers are proverbially scarce. Mr. Wills, I have heard, is successful in this way with a pure white variety, which he uses for bouquet and ceremonial purposes. I placed some cuttings of the double Pink Oleander in bottles for the Colonial Surgeon of Labuan in Borneo, when out there, and they rooted and flowered in ten weeks; but then this was under the equator, and with a temperature of 85°."—W. J. M., *Clonmel.*

FUNGI A RESULT, NOT A CAUSE OF DISEASE.

WILL my statement of results in dealing with Peach blister have any more weight with "C. P. P.," if I assure him that the positive cure of that disease is not confined to the Dr. Hogg tree? The Peach house is 130 feet long and contains the Dr. Hogg, two trees of Early Beatrice, and one of each of Rivers' Early York, Grosse Mignonne, Noblesse, and Barrington, all fan-trained upon the wall, all perfectly healthy, vigorous, and fruitful. All were affected more or less with blister every spring before the house was erected over them, and all have since been quite free from blister. These are not mere toy trees, but cover the entire length of wall, the Barrington covering 250 square feet of space, so that the trial is on a sufficiently large scale to be valuable. The lesson clearly demonstrated here is, that an unheated glass structure gives immunity from blister provided due care is taken with the ventilators during the prevalence of cold north-eastern wind in spring. It has done so for me for four consecutive years in this particular instance, and I may very confidently recommend the plan to the notice of your readers. If, as "S." asserts, well-ripened wood is a remedy for blister, why is it that trees growing here against a south wall with very little shelter from the east are almost invariably badly blistered in spring, while others upon another south wall having the shelter of coping boards and an east wall are only slightly affected by blister near the east wall, but show more and more blistered foliage the farther they are away from it, the tree at the west end of this particular wall having been twice almost killed by it? These are facts which I cannot ignore; and if upon the face of them I were to tell your readers that ripe wood was a remedy for disease, or that fungi was the cause of it, should not I then be "propagating errors?"

Evidently my assertion that what I have termed plague spots appear upon the Potato leaf before the spores of the fungus vegetates, is that to which my opponents take particular exception. After careful consideration I have come to the conclusion that here I am probably wrong, and may usefully so far modify my original statement by saying that in the Potato disease fungi is a result of decay. "Hence, then," they will say, "you agree that in the Potato at any rate fungi are the cause of disease?" Yes, I will concede so much. But let not "S." or "C. P. P." suppose that I can possibly think them right when they assert that they have perceived the presence of disease in the foliage before growth in the tuber has ceased. Like them I have seen diseased foliage before the tubers have attained their normal growth, but then I have always found that growth checked by ungenial weather, and once checked it never goes on again. There may be, and too often is, a subsequent lateral growth in the foliage and sprouting of the tubers, but that is a mischievous and wasteful growth, which may be classed with disease and avoided by early lifting.

What has been my motive in writing so much about the Potato and its disease? It is to induce your readers to lift the crop as soon as growth has ceased, and so altogether avoid the ravages of a disease for which there is no cure. Although I have been unsuccessful in persuading the slowcoaches to do this, yet I am glad to say many keen practical men have adopted the plan, and have been good enough to write me accounts of their success. My especial landmark that has stood me in good stead for so many years in this matter is the immunity of the plant from blight till there is a cessation of growth. It is a safe and sure guide that has never failed me. Let me now inquire what is the motive of "S." in this discussion? Granting him to be right in thinking fungi alone cause the disease, has he any remedy to propose? or can he point to storehouses full of sound Potatoes and thus give us tangible proof that he is a safe leader to follow? I may have blundered in my ideas about the disease, but I have saved the crop, and would rather have to acknowledge myself wrong in theory than in practice. Surely "S." will not attempt to deny that fungi is the result of decay. The common sight of fungi growing freely upon putrid meat, upon the bark of dead timber, upon rotten fruit and decaying vegetation generally, is sufficient proof of this; and although the Potato leaf is green, when disease attacks it its work is done, and it has begun to die, for that is the term used by the physiologist in speaking of the decay which ends in death.—EDWARD LUCKHURST.

[Our correspondent "S." stated last week that a "desire that doubtful statements should not go unanswered" induced him to enter on this discussion.—EDS.]

THE CONSERVATORY IN NOVEMBER.

AT no period of the year is the conservatory more enjoyable than during the months of November and December, consequently a few remarks upon the plants that may be employed in it at this time will be acceptable to some of your readers. Chrysanthemums will now be contributing largely to its brightness, and it is therefore advisable to ventilate night and day to prevent the plants being attacked by mildew; should it appear, however, dust the stems and leaves with flowers of sulphur. The objection to the use of much water in this structure often causes the flowers to suffer in size and also in duration, as they really need abundance of moisture. Epiphyllums make an imposing display, and may safely be placed in the conservatory whilst flowering. They are exceedingly effective for brackets or suspended baskets lined with moss so as to hide the pots; but they must not be overwatered or the roots will perish, nor must they be allowed to remain in the house too long or they will not do well afterwards. Primulas are very useful; and with Cyclamens and other dwarf plants should be placed in the lightest positions. Correas, Epacrises, and winter-flowering Heaths suffer little from a sojourn in the conservatory during their flowering, provided they have plenty of space, light, and air. *Salvia gesneræflora*, *S. Heeri*, and *S. splendens* are brilliant in colour and will do good service; but do not overcrowd them, as is often done, for such arrangements are not more telling, whilst the duration is shortened and the injury to the plants is permanent. Early-flowered *Cinerarias* are also bright. *Schizostylis coccinea*, with its Iris-like foliage and spikes of deep crimson flowers produced successively over a long period, and the white *Anemone japonica alba*, are indispensable. Good specimens of *Helleborus orientalis* are valuable, and the buds of *H. niger* and *maximus* are very pleasing.

Those already enumerated may be supplemented by flowering plants from the stove and Orchid houses occasionally, and will

make a very effective display. They do not suffer if they have been previously inured to a somewhat cooler and drier atmosphere.

Fragrant flowers must not be forgotten. Standard Heliotropes as well as bushes are always esteemed; a few pots of Violets will perfume a large house; and then there are Roman Hyacinths, Roman and Paper White Narcissuses, Lily of the Valley, and Roses. Well-berried plants of Solanums can be effectively employed. Climbers, such as Lapagerias and Tacsonias, will aid, but other vigorous roof climbers should now be pruned freely, so as to give as much light as possible to the plants underneath, as too much light can hardly be admitted even to flowering plants during the dull winter months. Neatness, tasteful arrangement, and variation in the material as regards position will do much to render even common plants attractive, and a little care in these matters is well repaid.—G. A. G.

ANEMONES.—No. 2.

SOME of the most attractive Anemones have been already briefly described, but I have by no means exhausted the list of those really worthy of a place in gardens. The following I have proved to possess merit of no ordinary degree, and as such I recommend them to the attention of all who admire and grow hardy plants. The notes will also be opportune, as the present is a good time for planting these flowers.

A. narcissiflora.—A very little known species, or it assuredly would be more grown. It is about 12 to 18 inches in height, producing in May a profusion of its umbels of beautiful snow-white flowers upwards of an inch in diameter. The root leaves are palmate, the segments being deeply toothed. The scape is erect,

Fig. 80.—*Anemone stellata fulgens*.

and bears an umbel of pure white and very showy flowers. May. Alps of Europe.

A. palmata.—This is a totally distinct species, and one of great beauty. It is a true Alpine, and should be placed on some flat piece of jutting rock, where the soil is both deep and rich. In such spots it will form fine clumps. It is usually about 8 or 9 inches high. The leaves are reniform, scarcely rising off the ground. The flowers large, nearly 2 inches in diameter, and golden yellow in colour. May. Native of the high mountains of Spain and North Africa. *A. palmata alba* differs only in the flowers being pure white.

A. pavonina fl.-pl.—It is remarkable that this plant, although common in the gardens of many parts of Europe, should yet be so very little known in England. The plant reaches a height of 6 to 9 inches. The flowers are borne well above the foliage, very double, and bright orange scarlet. A very showy plant. April, May, and June. South Europe.

A. Pulsatilla.—This species, which is found in some gardens under the name of *Pulsatilla vulgaris*, is distributed nearly all over Europe, and our own island also, though at the present time it is extremely rare in a wild state. Under cultivation it attains a height of 9 to 12 inches. Leaves pinnate; segments much divided into narrow lobes, which are densely hairy. Flowers slightly nodding, solitary, rich purple, clothed on the outside with long light-coloured silky hairs. It blooms from March to May. Europe (Britain).

A. ranunculoides.—Some few localities are recorded where this

Fig. 81.—*Anemone sylvestris*.

species is found growing in Britain, apparently wild, but there can be little doubt of its being only naturalised, and not indigenous. It resembles *A. nemorosa*, but its flowers are golden yellow instead of white. The plant seldom exceeds 5 to 6 inches in height, and should be grown in a chalky soil. March to May. Europe.

A. Robinsoniana.—This charming plant attains a height of from 8 to 12 inches. Leaves ternate, deep green. Flowers large, upwards of 1½ inch in diameter, bright azure blue. It should find a place in every garden where spring flowers are grown.

A. stellata.—This species has been long cultivated as a florists' flower, and the numerous varieties with their red, rose, or purple star-like flowers are beautiful spring decorators. They are scarcely so hardy as the varieties of *A. coronaria*, and therefore in severe weather should be protected by a little dry bracken or ling, each of which affords excellent protection for choice hardy plants, and do not present an untidy appearance. Neither do they like a heavy soil, light sandy loam suits them best. The flowers are nearly 2 inches in diameter and spreading, very variable in colour, but usually amethyst-purple. This and its varieties are often sold under the name of *A. hortensis*. April and May. South of Europe.

A. stellata fulgens (fig. 80).—This beautiful plant is found in a wild state in the mountains of Greece, and is perfectly hardy, the brilliant colour of its flowers rendering it one of the most conspicuous objects in the spring garden. In general appearance and habit of growth it resembles the species, but the flowers are of a uniform dazzling vermilion scarlet, the large tuft of black stamens at the base adding materially to its beauty. April and May. Greece and various parts of southern Europe.

A. sylvestris (fig. 81).—A charming early-flowering species, attaining a height of 1 to 2 feet, alike suitable for the border or rockery, and also grouping beautifully with others in the wild garden. Flowers large, pure white; before opening they are pendulous, which has earned for it the name of Snowdrop Anemone or Windflower. April and May. Germany, France, Northern Italy.

A. trifoliata.—This is a dwarf-growing plant seldom exceeding 6 inches in diameter. It somewhat resembles the Wood Anemone, *A. nemorosa*. Flowers pure white. April and May. Italian Alps.

A. vernalis.—A charming species, dwarf in habit but producing

very large flowers, which are white within, the exterior being tinged with purple and clothed with long brown silky hairs. Indeed, being a near relative of *A. Pulsatilla*, it possesses something of the peculiar hoariness which is characteristic of that species. It should be placed in some open spot in the rockery, where it has a good deep soil. April and May. Alps of Switzerland, and also the mountains of Norway and Sweden.—H.

THE POTATO DISEASE.

I AM sorry I have been unable to reply earlier to "AMATEUR'S" remarks. His request that I should account for the first appearance of the disease in 1846 is not reasonable. His view is that unless I can make my theory fit in with the facts of 1846 I am wrong. This is not good logic. My theory may fit all the facts, but if I do not know them I cannot use them. I hold that a firm grasp of all the facts is absolutely necessary to a sound conclusion; and because I believe there is an aspect of this most important question which has not had sufficient investigation, I write with the hope that some of the able men who read my remarks and who have the means of closely investigating them by observation and experiment will do so and give us the results. My own appliances and time are very limited.

I earnestly beg the closer attention of your very able correspondent "S." He has evidently missed my point. He has given us a lucid description of the normal conditions of circulation and evaporation of the plant, and his reasonings are based on these, hence they are inapplicable to my statement. My statement is that the disease is caused by the abnormal conditions of circulation and evaporation; in fact it is due to stagnation. The densely saturated atmosphere prevents evaporation and consequently circulation. More than this, the tissues and cells are gorged to bursting, disorganisation, or death, by a vapour bath continued too long. Portions of the plants are now disabled, and are successfully attacked by the fungus. Will "S." kindly master this view and let us have his opinion upon it? Practically we shall have gained a great deal by these papers if we can show the advantages of wide planting and employing means to dispose of the excessive wet.—AN INTERLOPER.

THE following books are missing from the LINDLEY LIBRARY, and of which no entry appears in the loan book—Brande's "Forest Flora;" Darwin's "Origin of Species," 6th ed.; De Candolle's "Memoirs et Souvenirs," 1862; Gray and Doehard's "Travels in W. Africa;" Hooker's "Flora of British India," Part 4; Humboldt, "De Distributione Geographica Plantarum," 1817; Lindsay's "Popular History of British Lichens;" Lowe's "Manual of the Flora of Madeira;" Neill's "Fruit and Flower Garden;" Matthew "On Naval Timber;" "Annales des Sciences Naturelles," 6me ser., tom. iii., 1876. Whoever may have any one or more of the above works in his possession is requested to return such at once to the Secretary of the Royal Horticultural Society, South Kensington.

— MR. SAM AINSWORTH sends us the following note on *GLADIOLUS NATALENSIS*:—"In your issue of the 4th inst. a correspondent writes an article upon the *Gladiolus*, but he has omitted an important form, *G. natalensis*, which was in commerce at about the same time as *G. byzantinus*, and I believe the forerunner if not the progenitor of *G. gandavensis*, the colours and growth being similar, only inferior in brilliancy to the first named."

— THE specimen at Kew of that rare but attractive tree *PARROTIA PERSICA* is now assuming the rich crimson tints which distinguish its foliage in late autumn when trained against a wall similarly to the specimen referred to. It is curious that when in the open the leaves fall comparatively early, and thus the tree loses its chief beauty. The first engraving of the *Parrotia persica*

appeared in the "Botanical Magazine," where the fine tints of the foliage with the bright crimson anthers of the flower are well shown. Dr. Hooker in describing it states that "it is one of the rarest trees in cultivation." Two plants, of which this is one, were sent to Kew from St. Petersburg about forty years ago, and it is surprising that it has not become more common. It is an ally of the *Liquidambar*, and is a native of the northern parts of Persia. It is quite hardy at Kew.

— IN the greenhouse at Holme Lacy there are now some fine plants of *SCHIZOSTYLIS COCCINEA*. The plants are grown in 9-inch pots, each of which supports from twelve to fourteen spikes. These brilliant masses mixed with other winter-flowering plants render the house very gay.

— A CORRESPONDENT states that *BOUVARDIA BRIDAL WREATH* is one of the best of winter-flowering varieties he is acquainted with. Its large trusses of white flowers, together with its free-flowering and compact habit, should make it a favourite of all lovers of white flowers.

— OUR correspondent "G. O. S." sends us the following amusing definition of ARTIFICIAL MANURE:—"One day this week our village schoolmaster, examining a reading class, asked the head of the class, What is artificial manure? 'Don't know,' said he, and the same reply was given by four other boys; but a precocious youngster, not yet in his teens, was equal to the occasion, and said, 'Please sir, it's the stuff they grow artificial flowers in!'"

— MESSRS. SUTTON & SONS of Reading have sent us some plants of their improved strain of *CYCLAMEN PERSICUM*, to show what can be done in about twelve months after the sowing of the seed. The plants are the result of seed sown on October 20th last year, and are, we are assured, a fair example of thousands now growing in their nursery, every plant of which is showing from fifty to a hundred flowers. The plants are not more remarkable for their fine flowers than for their thick, massive, and marbled foliage. They represent an excellent strain admirably cultivated.

— WRITING respecting the shrub *ARISTOTELIA MACQUI VARIEGATA*, our Clonmel correspondent states that there was a fine specimen in the grounds attached to Minella House that is now quite dead, though it survived the winter of 1878. "Both the soil, situation, and shelter were in its favour, and I should like to know if the shrub has survived elsewhere."

— WE have received information of the following GARDENING APPOINTMENTS:—Mr. Quintin Read, late of Pleasley Vale Gardens, Mansfield, has been appointed gardener to Frederick Mappin, Esq., M.P., Thornbury, Sheffield; Mr. W. Jordan, late gardener to J. Boustead, Esq., Cannizaro House, Wimbledon, has been appointed gardener to J. H. Nix, Esq., Silgate, Crawley, Sussex; and Mr. Peter Conway has succeeded Mr. Beach as gardener to the Marchioness of Bath, Muntham Court, Worthing.

— MR. LEE of Clevedon has sent a truss of his SEEDLING *ASTER*, referred to and figured on page 325 of our issue of October 7th, to show its continuous flowering habit. The truss is very fresh and fine, superior to the spray figured on the page indicated.

— A HANDSOME Conifer that is comparatively rare in gardens is *ABIES SMITHIANA*, of which there are several good though not large specimens at Kew. It is noticeable chiefly for the pendulous young growths, which impart a very graceful appearance to the tree. It is said to attain a height of 150 feet in its native localities in the Himalayas, where it is found at elevations of 7000 to 12,000 feet above sea level. It is known in some districts as *Morinda*, a native word signifying the nectar of flowers, an

appellation referring to the exudations of resin that are found upon the young cones.

— A GRACEFUL and distinct Fern is *ASPLENIUM CICUTARIUM*, with elegantly divided fronds somewhat triangular in outline, the pinnules being very neatly and regularly cut. It is a West Indian species and requires a stove temperature, but is otherwise easily grown.

— IN the current number of the *Journal of Forestry* is published an excellent portrait of Mr. WILLIAM M'CORQUODALE, the well-known forester at Scone, who was presented by the Scottish Arboricultural Society with a handsome testimonial on October the 5th as "a mark of respect and esteem on his attaining the fiftieth anniversary of his career as a practical forester." The testimonial comprised a gold watch and a purse of one hundred sovereigns, with a brooch for Mrs. M'Corquodale.

— AT the ordinary meeting of the METEOROLOGICAL SOCIETY, to be held at 25, Great George Street, Westminster, on Wednesday, the 17th instant, at 7 P.M., the following papers will be read:—"Table of Relative Humidity," by Edward E. Dymond, F.M.S.; "Rainfall in South Africa," by John G. Gamble, M.A., M.Inst.C.E., F.M.S.; "The Meteorology of Mackay, Queensland," by Henry L. Roth; "Thermometrical Observations on Board Ship," by Captain W. F. Caborne, F.M.S.

— IN reference to the rapidly increasing importance of THE FRUIT CROP OF THE UNITED STATES the following facts concerning the fruit farm of Robt. McKinstry, of Hudson, N.Y., will be instructive. His orchard contains about 33,000 trees, chiefly Apples, and he exports nearly 20,000 barrels of the latter fruit every year. Besides Apples and Pears he grows Cherries to a large extent, which are chiefly sold in the New York market at prices ranging from 7 to 18 cents a pound. Some of the Apples weigh 1 lb. each, and testify at once to the remarkable fertility of the soil and the skill of the cultivator.

— IN reply to the Rev. A. Fitch relative to the ORIGIN OF THE LAPSTONE KIDNEY POTATO, a correspondent obligingly directs attention to the following letter, which we reproduce from vol. xxv. of this Journal—

"Bramham, near Tadcaster, May 22nd, 1866.

"I, Joseph Hague, in the year 1827, then residing at Thorner near Leeds, planted two pecks of Potatoes, which I had sent me from Clap Gate near Harewood. These Potatoes produced an extraordinary quantity of fine berries, which induced me to try to raise seedlings from them. In that I succeeded, and selecting the two best from among the quantity I again planted the seedling tubers, but subsequently removed to Bramham, where I now reside. Having no garden connected with the house I then occupied, I took my seedlings over to Bardsey, and they were planted in my father's garden; and as he was the first to propagate them the general impression was, and is now, and is with many people to this day, that he raised them himself, but he never at any period of his life attempted to raise seedling Potatoes. I have five brothers who can all testify to the accuracy of the above statement. Mr. Fuller, florist, &c., Headingley near Leeds, but at the time gardener to G. Lane Fox, Esq., of Bramham Park, gave the Lapstone Kidney its name.—JOSEPH HAGUE."

Mr. Hague was a shoemaker, and was commonly called "Major" Hague. He died in 1850. His name is generally spelled and printed Haigh, but we presume incorrectly.

— THE same correspondent also gives a reference to the ORIGIN OF RIVERS' ROYAL ASHLEAF KIDNEY on page 173, vol. xx., where it is stated by "D., Deal," as being "probably a selected strain of Myatt's Prolific, raised by J. Ashwin, Esq.; and Mr. Rivers having carefully grown and selected the stock, it is now better known as Rivers' Royal Ashleaf." In 1870, page 124, vol. xviii., Mr. Rivers, in disclaiming the right of his name being attached to this Potato, gives the following as its history—"Some year or two prior to 1860 I was on a visit to the late James Ashwin, Esq., at Bretforten Hall near Evesham, who was an enthusiast in horticulture and agriculture. On passing by some Potatoes he

asked me if I had ever raised any seedlings in the course of my practice, and added that those I saw at our feet were seedlings raised from the old Ashleaf, and that they might prove of value. He had distinguished them as A, B, and C, and told me I was welcome to some tubers: these I received in the autumn. I found A was quite a curiosity, a true Ashleaf in miniature, not growing more than 6 or 7 inches high, and bearing a cluster of beautiful tubers. In the wet summer of 1860 this charming variety perished from the disease. B and C proved most robust and distinct, and one day attracted the notice of Mr. John Spencer of Bowood, who was walking with me. I at once called a workman to examine their roots, as they looked so promising. The end of it was our decision in favour of B, as the tubers were more regular in shape than those of C (I am quoting from memory). B was accordingly selected as a good Potato; and as Mr. Ashwin was deceased I decided to call it the Royal Ashleaf, fearing that the relatives of Mr. Ashwin might object to the prefix of his name."

RAISING GLADIOLI FROM SEED.

I AM sure Mr. Slater will not accuse me of captiousness if I venture to dispute the advice given by him as to raising seedling varieties of this beautiful autumn flower. He gives a list of varieties from which he advises seed to be saved. Now, there are only two of these that I would grow in my garden—Meyerbeer and Madame Furtado: the former still one of the most beautiful, although not so large as some of more recent introduction; and the latter I shall probably after this season discard. The fact is, that so great has been the improvement made both by Mons. Souchet and Mr. Kelway that the older varieties have been surpassed, and as Mr. Slater has discontinued their culture for some years he has not, of course, kept pace with the novelties that have been introduced. As I hope to give some fuller notes by-and-by before it will be necessary to purchase corms, I would merely say now that such varieties as Adolphe Brongniart, Horace Vernet, Baroness Burdett Coutts, Le Vesuve, Ovide, and Pygmalion would be much more likely to give satisfactory results than those which Mr. Slater recommends.—D., Deal.

THE NEWTON NURSERIES.

HORTICULTURISTS can scarcely pay a visit to the ancient city of Chester without inspecting the old-established nurseries of Messrs. James Dickson & Sons, which is situated close to the railway station, and can be reached in ten minutes' walk from the principal passenger station, and also in a few minutes from the Northgate Street station.

The main entrance to the nurseries for visitors is from Brook Lane by a broad and well-kept drive tastefully planted on each side with Gold, Silver, and green Hollies, which form a beautiful ribbon border with a background of Weeping Elms. The Hollies are most noticeable on account of their fine pyramidal shape and robust health. This main entrance leads to the offices, packing sheds, and glass houses. Before reaching them I was attracted by a large plot of Gladioli, which were in their best condition and very effective; numbers were also planted amongst choice ornamental shrubs. In the immediate vicinity of the offices the borders were gay with flowering and ornamental-foliage plants. I inspected the houses, and found a large collection of stove flowering and fine-foliage plants in robust health, all being in small pots. Small Palms are grown suitable for decoration, and for these Messrs. J. Dickson & Sons have a large sale. One house was devoted to Orchids, healthy and well-established specimens in 5 and 6-inch pots. Tree Ferns occupied a long house, principally *Dicksonia antarctica*, with a few plants of *D. squarrosa* and *Cyathea*, the former having noble trunks with a fine spread of fronds. Three or four houses were devoted to the cultivation of dwarf Ferns, all in excellent condition. Another house was filled with succulents in variety and of different sizes. Other houses were devoted to Heaths, Epacrises, Azaleas, and Camellias, as well as a general collection of greenhouse plants.

Vines in pots are largely grown, and about two thousand fruiting canes are annually prepared for sale. Frames and hand-lights are very numerous, as is necessary in nurseries of such magnitude, where Hollies, Rhododendrons, and other evergreen shrubs are propagated in such enormous numbers.

Near to the houses are the grounds appropriated to herbaceous and alpine plants, for which the nurseries are famous. The large stock of these plants both in pots and in the open ground alone

indicate that the demand is rapidly increasing. *Cypripedium spectabilis* grows luxuriantly in these grounds and proves quite hardy. These plants are in beds, and the crowns are covered with cocoa-nut fibre after the foliage has died, and in the severest weather mats or dried fern are thrown over the beds. The plants had made strong plump crowns, and a good supply of flowers may be anticipated another year. Good collections of Phloxes and Pentstemons are cultivated, and Irises are grown in great variety. The bulb ground must at times be very gay with the immense number of Lilliums and Narcissuses.

Passing to the large stock of Roses I noticed near a winding walk a large number of Clematises planted out for stock. Two plants of each variety are placed together and supported by large upright stakes when the plants are thoroughly established, and in flower they are very effective. Special attention is paid to Clematises, and a large stock is worked annually and grown for sale. The stock of Roses this year consists of 250,000, of which 60,000 are grown as standards and half-standards, and about the same quantity of dwarfs are grown upon the Manetti stock. Some 40,000 are worked upon the seedling Briar, and special varieties are selected for the purpose, such as La France, Capitaine Christy, and the Hybrid Teas; 20,000 Roses are upon their own roots. The soil in the Newton Nurseries is well adapted for Roses. They are planted in exposed situations, and no shelter whatever can be afforded. The plants make sturdy luxuriant growth, and are in excellent condition. Tea Roses are largely grown in 6 and 8-inch pots; the plants are grafted in the spring, and at the time of my visit they were free from mildew and in the most satisfactory health.

The fruit trees occupy about 15 acres, and a better grown stock it would be difficult to find. No time or trouble is spared to produce creditable specimens. The young trees are well balanced, whether trained in fan-shape, horizontally, or as pyramids. The large squares of pyramid Pears and Apples and their symmetrical shape indicate the attention that is bestowed upon them. The horizontally trained trees are equally good, and the large squares of fan-trained Cherries, Peaches, Apricots, and Plums are excellent. It is instructing to see the different effects the various stocks have upon the growth of the plants; this was especially noticeable in a number of maiden Plum trees on the English and French Paradise stocks and upon the Doucin stock, those upon the latter having made the strongest growth, while those upon the English had made the least.

The stock of forest trees is excessively large. About twenty millions of Larch are grown, varying in size from seedlings to strong plants 4 or 5 feet high. Sycamores are grown in large numbers, and I noticed some extraordinary seedlings that had made a growth of from 2 to 3 feet. The Sycamore is an admirable tree for planting by the seaside and in the vicinity of towns as well as in exposed situations, and it thrives in poor soil where many forest trees would die. Much attention is devoted to the forest department; and when Limes, Elms, Sycamores, Horse Chestnuts, and others attain a height of 5 or 6 feet they are planted in single rows and by the sides of the walks and drives, the result being strong stout stems and well-proportioned heads much better than if drawn up by one another as would be the case if planted together. Much ground in addition to better plants is saved by planting on the single row system. The trees are no detriment to the large flats of Larch and Firs that occupy the land close to them. Scotch Fir and Austrian Pines are grown at the rate of eight millions each, and twelve millions of Spruce Firs. The Corsican Pine is also very largely grown. About ten thousand *Cedrus Deodara* are grown from seedlings to well-developed specimens suitable for planting singly upon lawns or in the pleasure grounds, *Cupressus Lawsoniana* the same; and the choicer varieties, such as *C. crecta viridis*, *C. alba spica*, *C. lutea*, a beautiful Golden variety, and others, are well and largely grown. Yews, Thujas, Juniperus, *Retinosporas*, are also extensively propagated. Hollies are another of the special features, and the stock consists of thousands, and the variety called *Hodginsi* is largely grown. It is much hardier than the common Holly, and is by far the best Holly for exposed situations and the neighbourhood of large towns, Gold and Silver varieties being very good. Standards are also grown with the stems 5 or 6 feet high, suitable for planting as single specimens. Both common and Portugal Laurels are largely grown, the stock being about 120,000 of the former and 60,000 of the latter. Noticeable were some good standard Portugal Laurels with beautiful round heads, suitable for planting upon terraces, where they are very effective. There is a large stock of *Rhododendron ponticum*, and an excellent collection of hybrids; about 6000 are annually grafted. Round-leaved Privet, *Spiræa salicifolia*, Broom, and *Berberis* are grown in large numbers for planting as cover for game.

Amongst the Firs *Abies Douglasii* is largely grown, and a tall quick-growing Fir it is. Amongst *Piceas Nordmanniana* and *nobilis* are represented from seedlings to handsome specimens, also *Wellingtonia gigantea*; at the same time every new and rare kind is well grown and cared for.

The Nurseries are much exposed, and in consequence the occupants are not so likely to be damaged when planted in exposed situations, as is the case with hardy shrubs when raised in sheltered positions. Good practice in these nurseries is to allow each shrub as well as fruit tree ample room to develop into shapely specimens, which can never be the case when they are crowded together. A thorough system of lifting is practised with all plants that require it, and many are annually transplanted, especially after they attain a saleable size, so that the risk of lifting is reduced to a minimum. The enormous sale renders it necessary to move up the plants after the lifting season, or a large amount of land would be unoccupied, which does not appear to be the case in the Newton Nurseries. At the time of my visit the grounds were clean and in capital order. The large seed warehouse is in Eastgate Street, and the farm and implement warehouse close to it.—WM. BARDNEY.

ARCHING ROSES OVER WALKS.

WHEN pruning my standard Roses the winter before last I left two strong shoots on each of two trees, which were bent over and tied to a strong stake about 6 feet long on the opposite side of the walk. The result has been most satisfactory. Last season every joint or bud started and bloomed well. One was a *Gloire de Dijon*, and on this arch I counted at one time this summer sixty-four buds and blooms. The name of the other Rose I do not know, although it has been budded about five and twenty years, and the result of many inquiries, for the name only adds to the confusion, as I seldom obtain the same opinion from two individuals. Perhaps you could oblige me with the correct name, for which purpose I enclose a bunch of blooms. This has, perhaps, been more pleasing in the result of arching than the *Gloire*. At one time this summer I counted no less than 196 buds in different stages of development on a portion of the arch 4 feet in length, and at the present time there are over sixty buds looking very bright considering the severe frosts we have had.—J. HAM.

[The "bunch" sent is very fine, having sixteen buds and flowers. We showed it to Mr. William Paul, who recognised it as the old Bourbon Rose *Madame Desprez*.—EDS.]

THE CHAMPION POTATO AND ITS RAISER.

AT the present time, when the merits and demerits of this famous Potato are being so keenly canvassed in your Journal, it may not be out of place to put on record a short account of its origin and its probable effects on the future cultivation of our most indispensable root.

The history of the Champion can never be dissociated from the name of its raiser, Mr. John Nicoll, formerly gardener at Ochterlony in Forfarshire, and at present Superintendent of Arbroath Cemetery, where he has made his mark in the splendid way in which he has decorated and rendered attractive this city of the dead.

Mr. Nicoll, as his portrait will show, is a gentleman of mature years. His amiable and obliging disposition, and the unassuming way in which he has accepted the honours justly awarded him, are well known by all who have the pleasure of his acquaintance. Not so many, however, are aware of his extensive and accurate knowledge of the principles that have already issued in the production of at least one national benefit, and that promise to revolutionise the whole system of Potato cultivation in this country. To these principles I shall shortly advert. While others have usually been, in the production of new varieties of Potatoes, aiming at a type where form, colour, shortness of haulm, and in a less degree quality and prolificness, are the chief points, Mr. Nicoll has kept steadily in view a type that would withstand disease, yield large returns, and be of good nourishing quality. Those who criticise the Champion from a show point of view should bear this in mind, and remember that Mr. Nicoll's great aim has been the production of a profitable field rather than a garden variety. And if success in this and other lands has so undeniably indicated the Champion as "the poor man's Potato," it is safe to say that, spite of its shaggy growth and rough exterior, it may be hailed as the progenitor of a race the vigour and prolificness of which will enable us eventually to bid defiance to the dreaded disease.

The Champion was raised from seed gathered in 1862 from

three varieties of Potatoes planted with a view to hybridising. Mr. Nicoll does not now remember the names, but thinks they were seedlings raised by the late Mr. Paterson of Dundee. No particular care was taken to ensure a special cross, fertilisation having been left to natural means. Since then, however, Mr. Nicoll has taken the act of fertilisation into his own hands, and has now under trial a number of promising varieties of which the parentage is well known. The seed was sown at Ochterlony in 1863, and even the first year the produce was in some cases remarkably fine. Next year the collection of over one hundred sorts was planted with a view to selection, and the most

promising were reserved. For two years longer Mr. Nicoll continued to grow and select. In November, 1866, he left Ochterlony for his present situation, and from want of accommodation was reluctantly obliged to divide his collection among several of his farmer friends. One of these, Mr. Robertson of Newmill, Forfar, continued to grow and test the produce for a year or two with the result that one in particular so distinguished itself that it was given to the world under the name of Champion, and became a source of wealth to Mr. Robertson and not a few of the farmers of Forfarshire. An attempt was made, evidently under misapprehension, to deprive Mr. Nicoll of his just credit, but he is now

Fig. 82.—MR. JOHN NICOLL.

admitted to be the raiser of the Champion. Seeing that others had reaped the profits of what he had sown, it is not surprising that there were found among his friends souls generous enough to organise a testimonial in his honour, but it is surprising that the amount raised was so small—viz., a gold watch, a diamond ring for Mrs. Nicoll, and a purse of fifty sovereigns. This was, however, presented in January, 1879, before the Champion had earned its chief and recognised fame as useful food in times of famine, and before it was awarded a first-class certificate by the Royal Horticultural Society for its disease-resisting properties and good quality when exhibited by Messrs. Carter & Co. Had the testimonial been proposed a year later it would doubtless have assumed dimensions of a national character.

But Mr. Nicoll's work is not done. He has justly earned the position of an authority on the Potato question, and as such was

called on to give evidence in June last before the Committee appointed by the House of Commons to inquire into the causes of the Potato failures in Ireland. His evidence was mainly a narrative of the history of the Champion, but contained many hints derived from experience as to the best methods of combating disease. His main recommendation was—and he for one consistently follows it—to keep on raising new varieties from disease-resisting parents, and with a special view to hardiness. He did not claim for the Champion total immunity from disease; indeed, he warned the Committee that in all likelihood it, like Paterson's Victoria and others, would soon begin to fail and cease to be profitable after, perhaps, twenty years of public life—the years spent in propagation and selection not included.

As has been already mentioned, Mr. Nicoll has been engaged for many years in propagating new varieties, but in accordance

with his honourable character he has not yet yielded to the temptation to place any of these before the public as worthy of extensive planting. He candidly admits that for years he was baffled in his attempts to produce a truly meritorious variety. He has, however, hopes that the produce of seedlings of recent years may result in one or more varieties worthy of general cultivation. For instance, a seedling of 1878 has this season given a calculated result of no less than 26 tons per acre under garden cultivation, and 15½ tons under ordinary treatment in the field, in both cases without a trace of disease in the tubers. Some seedlings of 1879 have this season, under ordinary field treatment, yielded at the rate of from 5 to 11 tons per acre respectively, while the produce of seedlings grown only this season has been from 1 to 2 lbs. per plant.

The experience gained by Mr. Nicoll in his work may serve as a guide to less experienced aspirants, and may be briefly summarised by the remark that from all we know of Mr. Nicoll no one would rejoice more than himself, though others should succeed better than he. He states that "Propagating seed from the seed apple or plum must always be very uncertain, as Potatoes are exceedingly liable to sport, perhaps as much, if not more, than any other plant in cultivation which is grown for seed. Insects are not the only natural hybridisers. The pollen grains are so very small and light, that when shaken from the enclosing cells even a slight breeze of wind would carry them a considerable distance and deposit them on the gummed surface of the stigma, and so cause great variety in the contents of one plum." Still he is not certain that the stigma of a bloom that has been fertilised from stamens on the same plant will produce a variety of sorts. He finds that the Potato bloom, though possessing both stamens and pistil, does not ripen these simultaneously. The stigma is developed and fit for receiving pollen before the vessels on the anthers are opened for the discharge of the pollen grains. Thus fertilisation must be effected from older flowers on the same or some other plant by pollen conveyed by the wind or the agency of insects. Knowing this, and the proper moment for applying the pollen, Mr. Nicoll has obtained distinct crosses between the Champion and other more shapely and very hardy varieties, such as the Magnum Bonum. Great precaution needs to be exercised in keeping the produce of every seed thoroughly distinct, for the produce of one plum, especially if naturally fertilised, may give a hundred plants, no two of which may be exactly alike in all points. Even artificial fertilisation does not secure uniformity, though it greatly lessens the natural inclination to sport. The general type of the future Potato is no doubt fixed in the first tubers produced on the seedling plant if not in the seed itself, but considerable modifications may be looked for during the succeeding four or six years ere the type be permanently fixed. The most unpromising seedling may thus after all develop into a valuable variety. Coloured eyes will often disappear and coarseness of shape become toned down. Even yet one may readily observe the Champion itself slowly altering its character. It is not nearly so coarse in root and haulm as it was some years ago, while, on the other hand, occasional plants in a field may be observed reverting to their original type. Mr. Nicoll believes that were those occasional plants, the greenness of which after the first frosts in autumn makes them conspicuous among the others, carefully cultivated for a year or two, they would in all likelihood be found the means of continuing for another generation the native hardiness of the original.—WILLIAM RAITT, *Blairgowrie, N.B.*

PRUNING LUXURIANT ROSES AND VINES.

THE other day, when looking over an amateur rosarian's pets, a plant of Jean Rosenkrantz was pointed out as yielding only wood and leaves. The season's growths were at their base thicker than my thumb, and the general appearance of these stems immediately suggested the reason why flowers had not been produced. At the base of the shoots the buds could scarcely be seen. At the upper part of the shoots the buds had gradually become more prominent, till at the ends they were as prominent as those on any of the other Roses. To obtain a supply of blooms next season the tips of the shoots would merely require cutting off; but to make a permanent improvement at least one shoot would need to be cut well in, and then, instead of allowing the young shoots to grow as they pleased, their points would require to be pinched out when the young growths had attained a firm condition at least some inches above its base.

I have had a similar instance here with Grape Vines. A vine planted in spring with weakly canes, from which I expected only comparatively weak wood, have given us some canes where there are scarcely any buds at the base. The main leaves were forced off the stems at the end of August and the beginning of Septem-

ber; and now, instead of having to cut the canes down to within a foot of the ground as I had intended, many of them will have to be left several feet in length in order to secure a good leading bud. The lateral growths near the base are so pruned as to leave a bud to start, that the buried buds will not be missed in the process of thickening the canes equally throughout. Some canes intended for fruiting next year, the laterals of which have been kept regularly pinched, present a great contrast with the permanent canes in the matter of the buds. In this case the buds stand prominently out right from the base to the end of the canes. Similar cases will occur to many who have had practical acquaintance with young fruit trees, Plums being, perhaps, more given to produce this growth than other fruit trees—at least in the case of Plums the effects are more exaggerated. I thought a note on the above of more than passing interest just at present, when the time of pruning is at hand. A little attention to pinching in summer will always keep such growths away; but in cases where this has been neglected it is well to bear in mind that cutting them back merely causes a continuation of the evil, and in the case of young Grape Vines be most likely to cause a weakly growth instead of one of increased strength.—R. P. B.

MANCHESTER FRUIT AND VEGETABLE MARKETS.*

TIME was when this market was dependent upon Cheshire and the Lancashire bank of the Mersey for its supplies of fresh vegetables and fruits; but since the abolition of duties, improved steam navigation, and the more complete development of the railway system, no spot upon the earth's surface appears sufficiently remote to deprive the teeming populations of these districts of its productions.

But whilst these changes have proved a blessing to the community generally it will be said, probably, that they have tended to the injury of the native grower of many kinds of agricultural and horticultural produce. We know that that which is for the public good is oftentimes temporarily prejudicial to the interests of individuals. It is not the province of the writer of this article to point out any remedial measures that may suggest themselves, but he may be permitted to say that it seems pretty certain that the only change that can bring remunerative prices to the English grower—if they are not now so—lies between himself and the owner of the soil he cultivates. Diminished crops in this country, from whatever cause, no longer mean higher prices from the consumer. Abundance in any part of the world will flow into the scarcity of any other as surely as air rushes into a vacuum.

Other changes have also taken place. Ere the revolution in the sources of supply had begun the growers supplying this market brought their goods and disposed of them personally, now the great bulk reaches us by railway. The number of carts laden with their owners' produce which arrived in the market on the night of Friday the 8th of August, and before six o'clock on the morning of Saturday the 9th, last year, was 230. Their contents would probably be about one-eighth of the total supply brought for the Saturday's market. Very few large growers now sell their own goods; they are generally consigned to salesmen who have permanent standings in the market, and who charge a commission of 5 per cent. upon the sale of all goods entrusted to them. This system has its advantages, and perhaps not entirely free from occasional disadvantages. Doubtless the owner would frequently make more by his goods if he personally attended the sale of them; but then, to set against this, there is the time and money expended to enable him to do so, and therefore, all things considered, he is induced to save himself much trouble and employ the salesman.

In laying before the reader some of the chief sources of supply I will begin with our own country.

In the first three months of the year vast quantities of flowering Broccoli (erroneously called Cauliflowers by many persons) are received from Cornwall, very frequently 20 tons per day. The Cornish Broccoli are followed by extensive supplies from the midlands. The very best come from the neighbourhood of Northampton.

In March early Radishes are received extensively from Worcestershire. One salesman has sold three hundred hampers in one day. They leave Evesham and neighbouring stations in the evening, and reach Manchester at three o'clock the following morning in excellent condition. As I shall frequently have to mention Evesham as a source of supply I may here quote what a writer said of it fifty years ago:—

"The vale of Evesham is celebrated for the extreme richness

* Extracted from a Prize Essay by John Page, published by the Royal Manchester, Liverpool, and North Lancashire Agricultural Society by permission of that Society.

and fertility of its soil, which, by the successful mode of cultivation, produces earlier and more abundant crops than that of any other part of the country. Near the town, on both sides of the river, large portions of ground have been converted into gardens, horticulture constituting the chief occupation of the labouring class. Asparagus attains an unequalled perfection in the soil, and is extensively cultivated, and vegetables of every kind are, by means of the river Avon, conveyed hence to the principal towns in the surrounding district."

Since this was written capital, science, and industry have enabled the gardeners of the productive vale of Evesham to immeasurably increase their out-put, and the railway has come and superseded the river Avon in distributing it.

A great many spring Radishes are also grown at Wallasey, on the Cheshire side of the Mersey, and sent to the Manchester, Liverpool, and Yorkshire markets.

Watercress has become an article of considerable commercial importance. As an early spring salad it is a great favourite throughout these districts, and has a yearly increasing sale. It comes principally from Oxfordshire, where it is highly cultivated, and finds employment for a considerable number of peasants. It is cut in the afternoon, put on the train, and reaches the Manchester market at three o'clock the following morning. Many tons are sold here in one day. Thirty-five years ago the only supply of this article to Manchester was brought in a hamper or two by men, who gathered it from the Cheshire ditches.

The first supply of spring Cabbages comes from the far-famed Evesham. They are followed in a few days by those which are grown around London; then come the Lincolnshire and Cheshire Cabbages, and those grown in the neighbourhood of Warrington.

Asparagus is now plentifully supplied; the quantity consumed has probably quadrupled in the last eight years. One salesman has sold a hundred hampers here in one morning. Worcestershire (Evesham) and Northamptonshire are the chief sources of supply.

The first green Peas which appear in the market come from Algeria, Spain, and France in the order named. The first English from Evesham, the next from Nottinghamshire, and lastly from Yorkshire. From these two latter places the supply is enormous. One salesman has disposed of 1500 sacks in one day. The quantities grown in Cheshire and Lancashire are quite insignificant in comparison, and call for no further notice. The rule is to market Peas the next morning after they are gathered. If they stand in bulk more than one night fermentation sets in, and they are much depreciated. The rates for bringing green Peas to Manchester from Nottinghamshire are—for 2 tons and upwards, 13s. 4d. per ton; 1 ton and less than 2, 20s. They are put on the railway at Newark, Collingham, Swinderby, and Rollston.

From Yorkshire—Burton-Salmon, Selby, and neighbourhood, 11s. 8d. per ton; York, 12s. 4d.; Milford Junction, 12s.

I should have previously stated that the rate from Evesham is 20s. per ton.

In all cases the minimum weight for these rates is 2 tons, and lesser consignments are charged higher rates.

Six thousand five hundred sacks of Peas have been pitched in the Manchester market in one day.

The first new Potatoes seen in the market come from France in small quantities, and are always dear. In May they come from Cornwall and the Scilly Isles, and are followed by large quantities from Jersey. The Jersey Potatoes have very greatly improved in quality in the last few years, and the sale of them has consequently much increased. From the small beginning of a few baskets twice a week the trade has grown to many tons daily. One salesman has sold 40 tons of them in one day. The Jersey are closely followed by the "Ormskirk Pink-eyes." Of all early Potatoes these are probably the very finest flavoured. For many years their production was exclusively in the hands of small farmers and cottagers occupying the district lying between Southport and Liverpool; but of late years their cultivation has extended through South Cheshire, from the neighbourhood of Warrington away to Dunham-o'-th'-Hill. Much care is required and bestowed upon their production. They are kept indoors till they have sprouted, and then are carefully planted in "butts," over which straw mats are laid during the night and on cold days to shield them from the frost. These supplies are followed by those grown on both banks of the river Mersey, chiefly between Warrington and Barton. Vast quantities of excellent late Potatoes are also received from North-west Lancashire; indeed, it may be said that the county in which the tuber was first grown, after its introduction into England, has never since shown it any neglect. The once-popular "Fluke" Potato was raised from seed by John Turner, a labourer on the Langley Hill Farm, at Birch, near Middleton. It has now fallen quite out of favour, and is but sparsely grown.

All through the winter large quantities of Potatoes are received from Yorkshire, from Lincolnshire, and from Scotland. Most of these are those known as the "York Regent," than which no better late Potato need be grown. I have no means of ascertaining the quantity of Potatoes brought into Manchester in a year, but as all the populous towns by which it is surrounded draw their supplies from it the total quantity must be immense.

Beside the great fruit and vegetable market at Shude Hill there is an extensive Potato market on the premises of the Lancashire and Yorkshire Railway Company, in Oldham Road. This market is in the hands of the Railway Company, who pay the Corporation £1500 per annum for the privilege of holding it. Under the agreement Potatoes and Carrots only are permitted to be sold here, and none but those which arrive by the Company's line.

The largest quantity of new Potatoes brought into the market at Shude Hill in one week, from 1870 to 1879 inclusive, has been as follows:—

LOADS OF 18-STONE.

1870.	1871.	1872.	1873.	1874.	1875.	1876.	1877.	1878.	1879.
21,000	29,500	18,200	19,100	18,750	18,500	19,000	14,300	23,000	22,250

That the home grower of this popular and useful article of food has not a monopoly of its growth, however, the following figures will testify. They are copied from the Government return for 1877. I have been unable to procure last year's return, but I believe the quantity to have been greatly in excess of that in 1877. I learn from a private source that the quantity shipped from Hamburg alone last year was 4,592,270 cwts.

YEAR 1877—From

Germany	3,636,600 cwts.	Portugal	38,019 cwts.
Holland	729,941 "	Channel Islands	364,451 "
Belgium	933,021 "	Malta	63,253 "
France	2,079,185 "	Canada	84,756 "

making a total of 7,929,226 cwts.

The following are the rates for carrying Potatoes to Manchester from many of the places named:—Belgium, 14s. per ton; Hamburg, 22s. 6d.; France, 35s.; Jersey, 50s.; St. Malo, 50s.; Ayrshire and district, 21s. 8d. to 23s. 4d.; Perth and district, 25s. to 27s. 6d.; Goole, 11s. 10d.; Hull, 13s. 1d.; Keadby and Crowle, 12s. 2d.; and Holbeach, 16s. 6d.

Cheshire.—Delamere, 8s. 8d.; Mouldsworth, 5s.; Manby, 9s.; Helsby, 9s.; Tarvin, 9s.; Mobberley, 7s. 11d.; Knutsford, 7s. 11d.; Plumley, 8s. 4d.; Northwich, 8s. 9d.; Hartford, 8s. 6d.; Cuddington, 7s. 6d.; and Wallasey, 8s. 4d.—(*Royal Agricultural Society's Journal*.)

NEW AND OLD VARIETIES OF POTATOES.

WE have had a great addition to the number of new varieties of Potatoes of late years, respecting the merits of which all persons are not of the same opinion; some praise while others condemn the same Potatoes. I can only account for this difference of opinion by attributing it to variation of soil, situation, and method of cultivation. Much as I approve of new introductions, not only of Potatoes, but of other vegetables that may be really beneficial, I should like to see in the new something superior to the old. Now in new introductions of Potatoes, without looking for superior quality, I should be glad to find one that could equal a Jersey Blue or a Dunbar Regent for high quality. There are several old varieties that are really superior to any which have been raised of late years. The highest quality will always command the best price in the market, therefore we must consider the new varieties as novelties which it may be desirable to continue raising, in the hope that we shall some day be fortunate and find one of our seedlings that will equal in quality those that we have been endeavouring to supersede. Our patience and diligence have been great, but at present we can only congratulate ourselves that we have been trying for upwards of forty years to raise new varieties without having succeeded in producing one that will compare in quality with some that were in daily use before we began. We have obtained many useful varieties, I admit, but few that have made their mark in a commercial point of view like the York Regents, Flukes, and Dunbar Regents. When we shall be enabled to announce that our new introductions have obtained a better reputation and a higher standing than those that we have discarded we shall be enabled to report progress.—R. C.

HOLIDAY NOTES.

IN continuation of the notes taken during my holiday tour I now send a short descriptive account of Trentham and Keele.

TRENTHAM.

This being perhaps the best known, if only by name, I give it precedence as one of the best schools in the kingdom for thoroughly

practical horticulture in all departments. From an architectural point of view Trentham also stands pre-eminent, for it is said to have the finest front in Europe. Whether this be true I do not know, but I shall never forget the admiration I felt when some years ago, after walking through the woods and country lanes from Keele and having traversed the greater part of Trentham Park, a gentle sweep of the drive brought the Hall in full view. It would be impossible for me to adequately describe its beauties, and as I am neither a landscape painter nor architect I will not attempt to do so.

As this paper contains notes only, I shall only mention what I think is likely to be of most interest to your readers, for a full description of Trentham would require half the Journal. Flower gardening was at one time a great feature there, but it is no longer carried out as it used to be, although I need scarcely say that Mr. Stevens could undoubtedly render it as good as he did in times past were the means forthcoming. The plant houses, however, contain abundant treasures. In one of the stoves near to the bothy were some grand specimens of *Lælia autumnalis* 2 feet and more in diameter, in teak baskets and suspended within a foot or 18 inches of the roof glass, and shaded only from strong sunshine by means of sprays and boughs of Yew, thus giving them the nearest approach to natural shade. For size and vigour I have never seen their equals. The compost they were in was of the roughest description, consisting of fibry peat, lumps of charcoal, and sphagnum; stagnation was quite impossible. Out of doors, partially shaded by trees and shrubs, were two dozen extra strong plants of *Lapageria alba* in pots 14 inches in diameter. These I understood were for sale. The fine specimen *Camellias* in the large conservatory were in the most robust health and well set with buds. There was also a fine example of the charming *Luculia gratissima*, which produces its huge trusses of fragrant blossoms in the greatest profusion during the winter months. This plant should be more generally cultivated, as anyone who can grow *Camellias* well could succeed with it. The other permanent occupants were *Seafortias*, *Chamærops*, *Latanias*, *Rhododendrons*, *Roses*, *Acacias*, *Bamboos*, and *Hedychiums*, all in a healthy condition.

The large *Odontoglossum* house contained hundreds of *O. Alexandræ*, many of them in flower and all first-class varieties, *O. cirrhosum*, *O. Pescatorei*, *O. triumphans*, *O. hastilabium*, *O. citrosimum*, and *O. nebulosum* in large numbers. Mr. Stevens has a remarkably good variety of *Epidendrum vitellinum* which he grows extensively; the colour is unusually bright, and the sepals and petals of waxy texture. *Pleione lagenaria* (Indian Crocus) is well grown at Trentham, as are also *Calanthe Veitchii*, *C. vestita*, *Barkeria Skinneri* and *B. spectabilis*, *Dendrobium nobile*, *D. Wardi*, *anum*, and *D. Devonianum*. The copings in the new plant stove are very tastefully decorated with *Panicum variegatum* and *Adiantum cuneatum* placed alternately, the effect viewed from either end being most charming. *Tabernæmontanas* are evidently great favourites, for good specimens are to be seen by dozens growing luxuriantly. Amateurs who are fond of *Gardenias*, but are not successful in growing them, should give this plant a trial; the soil suitable for *Gardenias* will grow *Tabernæmontanas* to perfection. Adjoining the stove and separated by a glass partition is a new aquatic house, containing a tank in the centre 40 feet long by 8 wide and 3 deep devoted to the cultivation of *Nelumbiums* and *Nymphæas*. *Nelumbium speciosum*, the Sacred Bean of the Egyptians, was producing its lovely rose-tinted flowers in succession. One was open on the day of my visit, and measured 12 inches in diameter; after flowering the capsules are very interesting. Anyone possessing a stove may grow it if they choose, as the beautiful peltate leaves, of a rich metallic green, only reach the height of 4 feet. One-half of a 36-gallon cask, or a No. 1 pot with the drainage holes plugged up, will hold sufficient soil, which should be composed of loam, decayed manure, and grit or sand. Water should be added as the leaves develop until it reaches the top of the vessel; requiring plenty of light they should only be shaded from very bright sun. *Nymphæa cærulea* and *N. rubra* were also in flower in the same tank.

The range parallel to the last is devoted to the cultivation of Tomatoes, Melons, and Cucumbers; the latter had stems more like old Grape Vines than Cucumbers, they were so thick and knotted. Planted on hillocks as they are there, and in soil rich and lumpy, a sodden state of the border is nearly impossible. Melons are grown in the same way when not in pots, the soil being heavier in character: the variety principally grown is the old and well-tried Trentham Hybrid. The noted glass cases, or covered walls, designed by the late Mr. Fleming, contained a number of fine Cherries, Plums, Figs, Grapes, Peaches, &c., excepting the unheated portion of the glass wall devoted to the latter, where the fruit was scarce owing to the imperfectly ripened

wood of the previous autumn. The fruit in the heated section was plentiful and exceedingly fine. The crops of Grapes in the vineries were not so good as I have seen them at Trentham in August. The early houses were cleared of their fruit, and the Vines rapidly losing their leaves, the wood being thoroughly well ripened. Mr. Stevens has for some years furnished the back walls of many of the vineries with *Camellias*, where they flower very freely; anyone having the back walls of vineries unoccupied, and who require an abundance of *Camellias* for cutting, should adopt the plan. Bananas have a house to themselves about 60 feet in length and about 18 feet wide, and are planted out, a constant supply of fruit being kept up by succession plants. *Musa Cavendishii* is the kind grown. The old aquatic house contained fine plants of *Alocasia metallica*, *A. macrorhiza*, and some good *Crotons*. The roof and pillars were draped and festooned with the old but ever beautiful *Cissus discolor*; the walls of the tanks were furnished with *Selaginellas* in a dense carpet dotted with good plants of *Caladium argyrites* plunged, thus forming an edging of a very pleasing kind.

Out of doors were a number of Strawberries in pots, which for health and vigour could not be excelled, and I was informed that the only stimulant they had was night soil in the compost. This is a hint for growers.

KEELE HALL.

Keele Hall has long been famous for first-class Grapes and its grand Holly hedge. Under the skilful management of that able and respected horticulturist, the late Mr. Wm. Hill, these gardens assumed a prominent position amongst the best of the country; nor are they receding from that position, if we may judge by the work being done by their present excellent Superintendent Mr. J. Wallis, who gained much of his experience with his predecessor Mr. Hill. The early Peach house was never in better condition than when I had the pleasure of seeing it. To say the trees were in good condition would be faint praise; they were superb, not a trace of red spider or scale, every leaf healthy, and every shoot in its proper place; no crowding of bearing wood (the stumbling-block of too many of our otherwise excellent gardeners), nor yet any waste of space, but each shoot so placed that its leaves do not interfere with or overshadow the leaves of its neighbour, thus allowing free play of air and light upon the leaves, shoots, and last but not least the embryo buds in the axils of the leaves. Not one inch of the spacious trellises was unoccupied, and the trees were furnished from top to bottom with wood of uniformly excellent character. It is only due to Mr. Wallis to place this on record, for I have never seen Peach trees so good in any part of the country. The Peach and Nectarine trees in the later houses were bearing good crops of fruit of great size and excellent finish; specially noticeable were *Noblesse Peach* and *Impératrice Nectarine* in the Peach case. The Cucumber and Melon pits contained good crops, and in another pit was a fine batch of *Eucharis amazonica* plunged in leaves and producing their lovely white flowers.

Mr. Wallis is busily renovating the Vines and Vine borders, lifting and replanting such as are likely to give satisfactory returns, and planting young Vines in other cases. Those that were planted last year have borne several fine bunches, and have furnished the house with good bearing wood for the ensuing year. The old-established Vines have carried crops this year equal to those of preceding years; indeed, if there is any perceptible change in their condition it is for the better, which is very creditable to Mr. Wallis, considering the work they have done in the past under the manipulation of that champion Grape-grower Mr. Hill. The Black Hamburgs were very conspicuous for their regularity of bunch, large size of berry, and for the intensity of their colour and beautiful bloom. *Gros Colman* was also well grown and particularly well coloured for the time of year (August). *Muscat of Alexandria* had an exquisite amber colour, the colour so often coveted but so seldom obtained before the end of October. I may here remark that the piecemeal system of making Vine borders is carried out here, and one that cannot be too often repeated in your columns, for it is even now common to see new Vine borders made to their full extent at once, a practice that cannot be too severely condemned whether the border be inside or out. It may here be contended that where the border is more or less below the surface of the surrounding ground an open "pit" is undesirable, which I grant; but I reply that it is quite unnecessary to excavate at any time more than a foot over and above the space intended to be filled with new soil, and this foot of space I would strongly recommend to be left open if possible to the full depth of the border, not only as a means of drainage but as a means of aëration of the border, but if it cannot be left open let it be filled with the roughest of clinkers and brickbats and covered over thinly with soil.

The Camellias were in good health and well set with buds. I noticed on the roof of the Camellia house a large plant of *Tacsonia Van-Volxemi* bearing hundreds of its handsome flowers, and a quantity of fruit in all stages of development. I have never seen this *Tacsonia* in such fine condition; its ripe fruit may be used for dessert by those who prefer fruit of a pronounced acidulated character. I also remarked at the front of one of the Peach cases a batch of the brilliant *Lobelia cardinalis*.

The ribbon border in the kitchen garden was very beautiful, the lines being formed in the following order commencing next the path—*Viola lutea*, *V. Perfection*, *Pelargonium Waltham Seedling*, *Dactylis glomerata*, *Dahlia Zelinda*, and the back row consisted of *Tritoma Uvaria*, *Hollyhocks*, and *Dahlias* of taller growth placed alternately; the border viewed from either end had a most charming effect. There are beds in another part of this garden devoted to a few old-fashioned flowers, such as *Pentstemons*, *Carnations*, *Mignonette*, *Nemophilas*, *Candytuft*, *Sweet Williams*, *Calceolaria amplexicaulis*, *Pansies*, &c. A few yards further on and just outside the dressed grounds is the dell, the descent into which is by rough steps and well-worn narrow paths. The beauty of this spot amply repays a visit where *Lastreas* and *Pterises*, *Athyriums*, and *Scolopendriums*, *Campanulas*, *Brambles*, &c., all grow and commingle in natural luxuriance. The quietness of the place suggests the spot for reflection and repose. Returning to the nearest part of the dressed grounds a subterraneous passage and a bridge of a carriage way lead to the flower garden at the front of the house. The principal beds and chain borders were filled with the usual kinds of plants, and looked as pretty as could be wished.—J. U. S.

HARDY FRUIT GARDEN.

THE planting of fruit trees should be followed up as the condition of the soil permits, for from the superabundant rain strong soils can scarcely be planted with advantage. If the weather continues unfavourable it is better to defer planting until spring, otherwise autumn planting is preferable. The weather has also been unsuited for other work in connection with fruit trees, especially root-pruning, an operation that is best performed before the soil has quite lost the heat imparted to it by the sun. Careful root-pruning or lifting the roots of over-luxuriant and consequently unfruitful trees is beneficial, while weakly trees may be restored to a healthy condition by having the roots brought nearer the surface, and encouraged by supplying suitable soil, such as turfy loam, in which they can be laid. If the soil be heavy a portion of old mortar rubbish, road scrapings, or other gritty material may be added with advantage, but where the soil is light heavy loam and marl may be employed. In selecting young trees for planting it is of the greatest importance to obtain varieties which are known to succeed well in the locality, as there are both Apples and Pears which are excellent in the north and midland counties, but not satisfactory in the south, and *vice versa*. Pruning of Apple, Pear, Plum, and Cherry trees should now be proceeded with whenever the weather is favourable, so as to have work of this kind in as forward a state as practicable, instead of deferring such work until spring, when other work will be pressing. Pruning Gooseberry and Currant bushes should be proceeded with as opportunity offers, and a dressing of manure may be pointed into the soil. Fig trees against walls often suffer in severe winters if left unprotected. They should therefore be unfastened from the wall, the branches being tied up loosely in bundles and covered with clean straw and mats, or the trees may be thatched with straw or bracken, without removing the branches from the wall; but in either case the border containing the roots must be well mulched with littery manure.

FRUIT HOUSES.

Peaches and Nectarines.—The whole of the earliest forced trees having been properly dressed, the branches secured to the trellis, and the house thoroughly cleaned, the latter may be closed at the middle of the month, but air must be freely admitted in mild weather or when the temperature is over 50°. Do not employ fire heat except to exclude frost, as the slower the trees are excited the stronger will

be the blossoms. The inside border must be made thoroughly moist by an application of water, or in the case of weakly trees of liquid manure, and it will be advantageous to render it tepid. The outside border must be well protected with litter or dry fern, having wooden shutters or tarpaulin on the top to throw off wet and prevent the materials from being blown about. Trees intended to be started early in the year should have all necessary dressing, cleaning the house and keeping it as cool as possible. The lights may remain off until severe weather, as this will insure complete rest for the trees, and prevent the undue excitement which not unfrequently occurs when the roof lights are fixed. Trees in succession and late houses are retaining their foliage longer than usual, although the wood is apparently ripe and the buds prominent and abundant; but no further delay should take place in lifting and replanting, it being important that these operations be completed promptly after the wood is sufficiently ripened. The trees will then soon be ready for the final pruning—a very insignificant affair, as with proper disbudding, and allowing only those shoots to grow for future bearing that can be fully exposed to light and air, there is little need for the knife at the final winter thinning. We have not shortened a shoot for many years of Peach or Nectarines grown under glass, and the shoots 5 to 6 feet in length will afford a fruit at every foot length to near the point without any appreciable difference in the size or quality. The practice of cutting back the shoots to 10, 15, or 18 inches at most is now fast falling into disuse. The great point in Peach culture is the thorough exposure of the growth to the maturing influences of sun and air.

Figs.—Trees in pots intended to furnish ripe fruit in April should be at once placed in position—pillars of loose bricks being erected to stand the pots on, so as to bring them up to the required height in the pit. A good body of fermenting Oak or Beech leaves must be introduced between the pedestals and brought up around the base of the pots, but the heat there and at the sides of the pots must not exceed 75°, replenishing the leaves from time to time to maintain the bed at the proper level. The fermenting material will economise fuel, produce a moist genial atmosphere as well as mild bottom heat for the roots, and a rooting medium highly favourable to the swelling-off of the crop. If the trees are in small pots they may be placed on the surface of the bed, and as the heat declines plunge them. The temperature should be kept artificially at 55° by day and 50° at night, ventilating freely at 65°. Damping will only be necessary on fine days. Trees in succession houses should, when leafless, receive attention in pruning, an operation requiring some judgment. Trees with the roots restricted to small borders, if attention is given during growth to stopping and thinning the shoots, will need little pruning, whilst those that have a good run of trellis and the roots not so restricted will usually require a good thinning at the upper part of the trellis annually. Remove all elongated spurs, reserving where desirable those which are short-jointed and fruitful. The trees should after pruning be loosed from the trellis and washed with a brush, taking care not to injure the embryo fruit, thoroughly cleaning and if necessary painting the house. Point over the border lightly with a fork and remove the loose material, giving a top-dressing of manure about 3 inches thick. If the trees have been lifted the removal of the surface soil will not be necessary. The houses should be freely ventilated at all times except during frost.

PLANT HOUSES.

Mignonette.—This to do well in the winter season requires a light situation, otherwise it becomes weak. The plants intended for early flowering must be regularly tied up, placing neat stakes to the principal shoots. Water carefully, affording supplies only when necessary, providing those flowering or well advanced with a night temperature of 45°, and 50° in the daytime. Succession and late-flowering plants should have plenty of air, and no more water than will keep them from flagging, too much water and a close atmosphere being destructive to the plants.

Show Pelargoniums.—Keep show varieties as near the glass as possible, affording them plenty of air. Have them as dry at the roots as is consistent with their safety, to prevent their making sappy growth, over-luxuriance not being nearly so productive of bloom as

solidified growth. Tie out the shoots neatly as they lengthen, and destroy aphides.

NOTES ON VILLA AND SUBURBAN GARDENING.

KITCHEN GARDEN.

Laying-in Broccoli.—After having twice successively lost the greater portion, and in some instances the whole, of the Broccoli crops during the past severe winters, many will be inclined to take some precautions against a recurrence of the destruction. This is all the more necessary seeing what coarse succulent growth has been made by the Broccoli and other members of the Brassica family this season. The part most susceptible of injury by frost in the Broccoli are the long exposed stems; protect these, and the number of fatalities will be considerably diminished if not altogether prevented. There are several ways of doing this, all of which, however, will materially reduce the size of the heads; but then small Broccoli are better than none—many, indeed, prefer small heads. The most laborious plan, but which is recommended especially when the plantations are much scattered about, is to lift the whole with as good balls of earth about the roots as possible, and to bed them all in together where they can be conveniently and roughly protected. The site selected should be perfectly open, and if the soil be at all poor should have a quantity of decayed manure worked-in as the process goes on. Commence by first opening a rather deep and sloping trench, then lay in the plants so as to face either the north or west rather closely, and to such a depth as to insure their being buried up to the crowns, with the soil thrown from the next trench. The rows of plants should be well up together, but the crowns ought not to overlap. The last trench opened to be filled with the soil wheeled away from the first made. The roots should have the soil with the manure, should this also be used, packed rather firmly about them, and into this they will soon spread. The advantages of bedding together is that it admits of the crowns being also protected with bracken, rough litter, or other light material should severe frost appear imminent. Veitch's Autumn and Snow's Winter Broccolis are much liable to injury by frosts, the former variety especially; and some or all of these may with advantage be bedded-in, either in the open ground or in large frames, and be protected with mats or lights as the case may be. The rows of other varieties, if those in charge are dubious about the wisdom of lifting, ought at any rate to be heeled over where growing, the only notable exceptions being Osborn's White and similarly dwarf-growing varieties. Commencing at the northern side of a row, take out a large spit from near the first plant, distributing this where the plant will be laid, then thrust in the spade to its full depth on the opposite side, and about 9 inches from the plant, and steadily bring the handle forward so as to force the head of the plant on to the little mound of soil previously formed. Work the surrounding soil up to the ball, then take another spit of soil from the front of the plant next in the row, and with this cover the stem of the previously moved plant, going on in this manner to the end of each row. In this instance the check to the growth is less perceptible, a good ball of earth being easily moved with the roots. Rapid thawing is very injurious, and it is to prevent this that the plants are made to slope to the north and away from the direct rays of the sun.

Cauliflowers.—Any of these that have formed heads may be lifted and bedded-in in an open shed, or be hung up in a cellar, and in either instance will keep for some weeks. Much injury has already been done to them by frosts, and now that the winter has apparently set in no risks should be run by leaving them to grow to their full size before lifting. The autumn-sown plants pricked-out in boxes or frames should not require much protection for some time, and ought to have the lights off them on all fine days, and plenty of air at other times in order to prevent them making much delicate growth.

Lettuces.—These, again, that are to be wintered in frames should be kept as hardy as possible. They are really hardier than many are aware, and the market gardeners in the south have during the past month put out large breadths, principally of hardy Green Cos varieties, with every confidence in their power to withstand any kind of weather that may be experienced during the winter. Luxuriant growth is quickly damaged by frost, but this may easily and should

be checked by transplanting. They require to be planted rather firmly.

GREENHOUSES AND FRAMES.

Chinese Primulas.—These are now commencing to brighten the greenhouses and conservatories. To bring out their colours and to strengthen the trusses of bloom give them a light warm position (a swing shelf near the glass suits them in this respect), and weak liquid manure occasionally. Much moisture about the roots and a low temperature is very likely to cause them to canker at the collar, this being followed by a loss of the lower leaves and ultimately of the plants. They must not, however, be allowed to become dust dry, the secret of success being to give a thorough watering when dry, regular or daily dribbles doing the mischief.

Persian Cyclamen.—Much of the foregoing also applies to these. They should, at all events till they are nearly at their best, be either arranged in groups on a light airy stage, or be placed on a shelf near the glass. If in the front rows among the ordinary occupants of the house they are very liable to become spindly, weak, and insect-infested.

Zonal Pelargoniums.—Sturdy plants both of the single and semi-double flowering varieties that have been specially prepared are now very effective. Keep them in a dry, open, warm position, and they will continue flowering for a long time; and do not supply water too freely, as that will induce strong growth at the expense of the bloom. Standards are really the best for winter flowering, simply because of their being well elevated and exposed, causing the formation of most sturdy and floriferous growth.

Browallia elata.—Plants of this are now at their best, the light sprays of small bright blue flowers being very effective among the Pelargoniums and Salvia splendens. When cutting the Browallia, and also the Salvias for vases, cut over a whole plant at a time, which will induce them to push up a second crop of bloom. They will also be encouraged in this by an occasional use of liquid manure. If a genial temperature is maintained with the help of a little fire heat, so as to prevent the temperature from falling below 55° in the daytime and from 45° to 50° by night, all the foregoing will bloom much more freely, and other kinds will be forwarded considerably. Solanum Capsicastrum ought also to have the benefit of a little fire heat to properly ripen their fruit. Tepid water should always be used in a warm house.

Cinerarias and Calceolarias.—These will still thrive in frames, but must be carefully protected from frosts. Perhaps the best place for them now is on a cool bottom well away from the hot-water pipes (the latter especially will do well on shelves near to the glass), in a house where no fire heat is given beyond enough to keep out frost. Any Calceolarias yet in seed pans may be potted off and others be shifted on before they are much rootbound, or otherwise they will flower prematurely. A few of the latest Cinerarias may yet receive another shift; they are sometimes very useful in 5-inch pots. Drain the pots carefully and use rather light loamy soil. Avoid shading either kind with other plants, and also crowding, and attend well to the watering.

Violets and Auriculas thrive under much the same conditions as the preceding, crowding and fire heat being injurious to both. Do not allow them to become dry at the roots, and pick off all decaying leaves.

Fuchsias.—Old plants that have flowered, and which are required to bloom early, should now be partially dried off, but they must not be allowed to become dust dry or they will not start freely. Place them where they will be cool but safe from frost, and not, as is often the case, beneath stages exposed to the drips from other plants. Plants from cuttings struck in August should now be shifted into 6 or 7-inch pots, and be placed near the glass in a house with a temperature of 45° to 50°. Tie up and stop the leading shoots according to the habit of the variety.

TRADE CATALOGUES RECEIVED.

Thomas Laxton, Bedford.—*List of New Peas.*

Francis and Arthur Dickson & Sons, The Upton Nurseries, Chester.—*Catalogue of Forest and Ornamental Trees.*

Dickson & Robinson, 12, Old Millgate, Manchester.—*Catalogue of Roses.*

TO CORRESPONDENTS.

Address (E. Hill).—The address you require is Messrs. Arnold & Sons, 35 and 36, West Smithfield, London.

Books (H. Martin, Paris).—There is no single work published in England that fully treats on all the subjects you mention, but much of the information you require may be obtained from the following:—Paxton's Botanical Dictionary, Johnson's Gardeners' Dictionary, and the Treasury of Botany. A good work of reference for the synonyms of plants is Steudel's Nomenclator Botanicus. (C. F.).—There is no book published such as you appear to require, but the subject to which you refer shall have our attention. (W. R.).—"The Eatable Funguses of Great Britain" published at this office, price 7s. 6d., contains a number of coloured plates of the most important edible species.

Climbers for a Small Conservatory (E. A.).—Lapagerias rosea and alba, Passiflora caeruleo-racemosa, and a Maréchal Niel Rose will be suitable. Tacsonia Van-Volxemi and T. exoniensis are free-growing and effective climbers; and very beautiful are such free-growing Fuchsias as Corallina and Lustre when they are trained to a roof.

Vines (Idem).—Your house will not accommodate more than eight Vines, the two at the ends being 18 inches from the glass, and the others 3 feet apart. The Black Hamburgh will prove by far the most satisfactory, and we should not plant many others. A good white companion for it is the Buckland Sweetwater. Vines do not succeed well on back walls when the roof is shaded. You may try the Black Hamburgh and Alicante.

Mildew on Roses (Castlewellan).—We should prune the plants, removing the foliage, and dress the branches with sulphur made into a paint with a solution of soft soap. A little clay and lime may be added to make the mixture adhere, and if the colour is too light it may be darkened with soot. Apply the mixture with a soft brush.

Horn Shavings (J. P.).—They are valuable for mixing with the soil of Pelargoniums and all plants needing manurial aid; if used too freely, however, they promote the growth of foliage at the expense of flowers. Used in the same proportion as bone meal the results are similar.

Stephanotis Flowers (J. Gibson).—You have evidently a free-flowering form of this plant, and also a good one, for the flowers sent are very fine, especially when we consider the plant has been flowering since March 10th, and is likely to continue for an indefinite time. Your mode of culture is good as well as the variety.

Erratum.—By a printer's error the name "Mattot's" Pearmain Apple appears in the report of the Pomological Meeting at Hereford on page 418; it should have been printed "Mabbot's" Pearmain, a variety that is being distributed by Mr. George Paul of Cheshunt.

Fig for Wall (G. W., Cardiff).—You cannot plant a more useful variety than the Brown Turkey. Mix plenty of lime rubbish with the soil, and make it very firm to prevent luxuriant growth.

Potatoes (J. S. D.).—The Crystal Palace Kidney, Edgcott Seedling, Huntingdonsbire Kidney, Beaconsfield Kidney, and Yorkshire Hero are all forms of the Lapstone Kidney, and have no doubt been selected from it by different cultivators.

Exhibiting Apples (A. Maw).—If you write to Mr. Barron, the Royal Horticultural Society's Gardens, Chiswick, London, he will supply you with all necessary information for submitting them to the Fruit Committee.

Vines Outside the House (A Constant Reader).—It is important that the wood of the Vines be well matured, and then they may be safely turned outside the house, especially if they are protected with hay bands during severe weather. Prune them immediately the leaves have fallen. When placed in the house in the spring they must not be submitted to a stove temperature at first; 50° at night will be quite sufficient until the buds have fairly started.

The Vegetable Insect (Deodar).—It is probable that what you term "an insect which buries itself in the earth and subsequently becomes a perfect plant" is the Cordyceps or Sphaeria Robertsii, of New Zealand, which is known there as "the vegetable caterpillar." It was figured and fully described in No. 881, vol. xxxiv., which you can obtain from this office post free for 3½d. in stamps.

Vine Roots (C. B. M.).—If you will inform us in what respect your Vines are satisfactory—stating the condition of their growth and foliage, and of what ingredients the border is composed—we shall be better able to suggest the cause of the slight injury of the roots. If, however, you think the Vines are affected with the Phylloxera we can inform you that there are no symptoms of that pest on the roots now before us.

Rebuilding Walls (A Gardener).—We never undertake to give estimates of the cost of work of any kind, as this necessarily varies in different districts. No one can determine the cost of such alterations without seeing them, and you cannot do better than invite two or three other builders to examine the walls and submit tenders for their restoration; you will then get the work done at the lowest cost, which we presume is what you require.

Fruit Trees (W. W. A.).—If you will state the number of trees or varieties you require we will name some that we think will be suitable; without this information you will perceive that we are not able to give you a precise and satisfactory reply, as we should perplex you if we named many more varieties than you wish, and disappoint you if we did not name sufficient. The Pear you have sent shall be examined, and the name given if possible.

Vines for Planting (James Bellon).—The following advice of an excellent cultivator will answer your question—"Those who intend planting a vinery, and who have not yet obtained the young Vines, should purchase them at once from a respectable nurseryman, and pay the highest price for them; a shilling or two saved in the price of a Vine must be considered a small matter in comparison with having a large number of failures from planting badly-grown canes. Those who rush to the cheapest market for their goods generally pay most in the end. When the plants are sent home they should be kept until planting time in a cool house where frost cannot injure them."

Potting Lilium auratum (D. Vickers).—Turn the plant out of the pot,

and remove as much soil as you can without injuring the roots. As the bulbs are small, 7-inch pots will be sufficiently large. Drain them well, and use a compost of two parts light turfy loam, one part sandy peat, and one part leaf soil or old cow dung, with a free admixture of sharp sand. Pot so that the crown of the bulb may be about an inch below the rim of the pot, and when the plant has made a shoot a few inches high top-dress with rich compost. Keep the plants safe from frost, and the soil only just moist, but when the plant is growing freely and flowering water copiously. It cannot have too light or airy a position.

Oporanthus luteus (C. M. Major).—We were unable to ascertain the name of the specimen you sent in time for the last issue owing to the flowers being in a great measure faded, but from careful examination of such characters as were discernible we believe it is the Amaryllidaceous plant named above. It is a native of South Europe, and is first recorded in cultivation in England about the close of the sixteenth century. It is figured in Mrs. Loudon's "Flower Garden." For cultivation in borders there are few autumn-flowering plants of its class that equal it. Although so old, it is not so common as might be expected.

Eriobotrya japonica (Barron).—The specimen you sent was a leaf of Eriobotrya japonica, the Japanese Loquat, an evergreen tree included in the natural order Rosaceae, and closely allied to the genus Mespilus. The fruit is about the size of a large Gooseberry, yellow and downy, somewhat resembling the Apple in flavour, though Sir Joseph Banks considered it equal to the Mango. As the name implies it is a native of Japan, whence it was introduced about a hundred years ago. In the southern counties of England it succeeds well trained to a wall, a south aspect being particularly favourable, but further north the protection of a greenhouse is requisite. The flowers are produced early in the year.

Destroying Slugs (A Lady Gardener).—Slugs are easily reduced in numbers if simple means are adopted at the right time. Fresh strong dry guano will kill slugs, as also will freshly slaked lime, but old lime has little effect on them. It is, however, obviously no use applying either the lime or guano in the daytime when the slugs are resting in their haunts, but the dusting should be done about an hour after dark when they are feeding or in search of food, and then again at daybreak during mild weather. Small heaps of brewers' grains and bran laid on the beds will be covered with slugs an hour or two after dark, and a covering of lime and salt will destroy them. By persevering with this practice slugs may be considerably decreased in numbers. If slugs and grubs eat the bulbs in the soil each bulb ought to be surrounded with sharp sand and wood ashes.

Destroying Earwigs (Idem).—If you refer to page 233 of the issue of September 9th, 1880, you will find Mr. Abbey has proved that if about 8 ozs. of nicotine soap are dissolved in a gallon of water, the solution, when applied with a syringe, instantly kills all the earwigs that it reaches. Syringe your rustic trellis thoroughly, and any solution falling to the ground would have the effect of checking the movements of slugs there also.

Espalier Trees Cankered (F. J.).—In all probability if you cut the tree down as you propose, and also replant it in good soil, the future growths will be healthy. It would be better, however, to transplant the tree this year, only partly cutting it down by removing the most cankered portions, as the foliage of next summer would incite root-action, and that being insured you may then cut the tree down next autumn. We have seen cankered trees rendered healthy by replanting and judicious pruning without cutting them down entirely; but perhaps your tree is too seriously affected to be renovated in this manner.

Treatment of Nepenthes (Beta).—It is probable that the cause of the shoots decaying is too low a temperature and excessive stagnant moisture. Nepenthes are natives of tropical swampy regions, and consequently though requiring abundance of moisture they also need a moderately high temperature. It should be as equable as possible, about 70° being suitable; rather lower in winter, but not below 65° if possible, and on no account below 60° to ensure the health of the plants. They should be provided with a compost of fibrous peat and sphagnum well mixed, and if grown in pots these must be efficiently drained; but as little depth of soil is necessary the plants thrive well in baskets suspended from the roof of an arched house or stove. Supply water most freely during growth and in hot weather, but at this time of year much less is required. Syringing the growth and foliage is also beneficial during the summer, or at other times in clear warm weather, provided it be done early in the day.

Fallen Leaves (J. G.).—If your Conifers are healthy we should let the leaves remain, as you do not object to their appearance. They will not absorb all the rain that falls during the winter months, while, as you observe, they keep the soil moist and cool in summer, and exclude frost in winter; they have also a manurial value suitable for the trees. If the specimens are not healthy you may remove the leaves and spread fresh soil and manure on the space they occupied. The leaves would be useful if dug into the ground, especially if it is heavy, intended for Potatoes.

Plants, Roses, and Cucumbers (T. K.).—We presume you have a stage in the house that is not shaded with the Cucumbers, and also shelves near the glass. In such positions you may grow all the plants you name, also Aehimenes, Eucharises, Papanatums, Gloxinias, Amaryllises (Hippeastrums), Poinsettias, Euphorbia jaequinæflora, Epiphyllums, Gardenias, Gesneras, and nearly all stove plants having ornamental foliage. Few plants besides Ferns will succeed beneath the Cucumbers. The house will be too hot for the Maréchal Niel Rose; but at Lambton Castle Mr. Hunter grows such Tea Roses as Isabella Sprunt, Duchess of Edinburgh, Safrano, Niphetos, Madame Falcot, and Vicomtesse de Cazes planted out in a trough of rich soil at the back of a Pine stove, where they form quite a hedge, and produce hundreds of flowers during the winter months. You might try the experiment on a small scale if you particularly desire to have Roses in the house, but it is not certain that you will succeed so well as such a good gardener as Mr. Hunter does.

Manuring Roses (Idem).—Pig manure is excellent for placing over the roots of standard and other Roses in the open ground at this season of the year. Spread it 3 inches thick, and as far as the roots extend. If your Roses are not growing satisfactorily you may sprinkle the soil lightly with the mixture of poultry manure and soot before the other manure is applied; it may also be applied to Roses and most other crops during showery weather in spring with great advantage.

Acacia pubescens (Mrs. Gray).—This species is by no means common, and if this really is the one you have it might be increased by either layers or cuttings, but the latter is the better and generally the more successful mode of increase. The young half-ripened growths should be selected for the purpose, preparing them similarly to other cuttings, and insert them in a compost of finely sifted loam and abundance of silver sand in a well-drained pot. Cover the pot with a bellglass, and plunge it in a propagating frame in a temperature

of about 65° or a little more. The plant has been known in this country about seventy years, and therefore it is not a novelty. Many exotic plants fail to produce seeds under cultivation; some from the absence of insects that assist in transference of the pollen, and others owing to the pollen itself being so altered in its constitution as to no longer possess the requisite fecundating property.

Destroying Thrips (C. F.).—When plants are so much infested as yours appear to be much perseverance will be necessary to completely eradicate the pest. All the plants should be sponged with a solution of Gishurst compound, nicotine soap, or some other insecticide; or 3 or 4 ozs. of soft soap dissolved in a gallon of water, adding thereto a quarter of a pint of tobacco water, will answer your purpose. They should all either be repotted or have the surface soil removed, adding fresh compost; the pots should also be washed, and every portion of the woodwork of the house. In the spring the plants should be syringed once a fortnight with an insecticide, or be fumigated. By carrying out some such practice as this you may succeed in extirpating the insects, or so reducing the numbers that they will do little injury. The Vine rods should be washed with strong soft-soap water, brushing them thoroughly with the solution as hot as the hand can bear it.

Names of Fruits (R. E. M.).—We are sorry we cannot name either of your Apples. They are quite new to us. Are you sure they are not seedlings? The large conical one appears to be a good late variety. (T. S. Ware).—You have not put any marks on the specimens. The highly coloured russety one is Hambledon Deux Ans. The other two we do not know.

Names of Plants (J. W. Collett).—The specimen was very much withered, owing to its having remained in the post over Sunday, but it resembled an Alonsoa. (G. Lee).—*Oporanthus luteus*. See the reply to "C. M. Major."

POULTRY, PIGEON, AND BEE CHRONICLE.

BREEDS OF CATTLE ADAPTED FOR DAIRY FARMING.

(Continued from page 426.)

ALTHOUGH we have previously entered into some details connected with the breeding and rearing of cattle as well as their daily management we have still various comments to make upon the same subject. It is notorious that the experiences of dairy farmers are often contradictory, arising from causes which cannot be here all enumerated. Our remarks will, however, be based upon our experience, and also upon the evidence of the best dairy farmers. Sometimes we have heard the remark that surely such small matters of detail cannot all be essential to dairy management. To this we reply that they are necessary, and it is in neglecting them that many failures occur.

The regular breeding of cows is so important, not only for a regular supply of milk, but the quantity of it also, that nothing should be allowed to interfere with continuous breeding which it is possible to prevent by judicious attention. In some herds cows do not breed again until their calves are weaned; in others it makes no difference. The weight of evidence is in favour of the suggestion that it is the companionship of the cow and her calf rather than the fact that the cows are not hand-milked that delays their breeding; it follows therefore that the calf should be removed early from the dam. In the case of heifers, however, which suckle calves during the first year they should be allowed to do so only twice a day, and at the usual time of hand-milking. We are of opinion that some of our best cows ought to be milked three times during the twenty-four hours instead of only twice, for the flow of milk is often checked or cannot be retained in the udder, and is therefore wasted. We had an instance in our dairy of an Alderney cow which for a time produced sufficient milk to make 14 lbs. of butter per week; but we believe that 16 or more pounds might have been made if the cow had been milked three times instead of only twice, as the milk often passed away in a wasteful stream before the time of milking. Hand-milking is frequently very imperfectly done, and because the back teats of the udder usually yield most milk they are oftentimes milked out first; but practically both teats should be milked simultaneously, and for want of this precaution we often notice that the front

part of the udder yields but little milk, and the udder falls down behind into what is termed a ean-bagged udder. This alteration of the shape, it is contended, diminishes the quantity of milk secreted in the udder; in fact, it is rare to see a good milch cow excepting the udder stands well forward. It is even stated that defects in the shape of the udder thus produced can be handed down to succeeding generations if such neglect and mismanagement has continued for any lengthened period. This, however, we believe to be based on a theory not generally acknowledged by practical men or supported by the skill of professional physiologists. Heifers with their first calf having any imperfections should be sold or fed for the butcher.

The general health of dairy cows will greatly depend upon the feeding and water, as well as occupying a healthy habitation in either boxes or stalls. We will take first the feeding, which must be regulated in a great measure by the way in which the milk is to be turned into money. If the milk is sold into the towns they may be fed upon inferior substances, having reference to the quantity of the produce rather than the quality, grains for instance being one of the best foods for a milking dairy, but by no means admissible in a cheese or butter-making dairy. Still the advantage of a milk-selling dairy has its value, for nearly every kind of vegetable produce will furnish milk for sale, whereas if made into butter or cheese it would seriously affect the flavour; in fact, this is one reason why so many inferior articles are found on the market, the milk from which they are made being impure, either from the effect of the food or bad and unwholesome water. Again, boxes or stalls with correct management are of the highest importance, for we have no right to expect that the animals can enjoy uniform good health, or that the milk can be obtained pure, whilst foul air prevails and circulates through the buildings, for there is positively nothing which is more susceptible of prejudice in its contact with ammoniacal vapour or impure air of any kind than milk, especially whilst warm and fresh. We shall omit observations here relative to the advantages of construction of the accommodation for the cows under cover, for we have recently considered the subject most fully under the heading of "Shed Accommodation for Cattle" in this Journal, and concluded on the 30th of September last, page 316.

Having now referred somewhat in detail to the management required to rear cows adapted for the dairy, we shall refer to the stock as offered for prizes at the recent Dairy Show. Most of our observations have partaken of comparisons between pedigree Shorthorns and those of an ordinary character, as fitted for dairy purposes. We find in confirmation of our own opinions that the pedigree stock at the Show received no prize in the milking competition. It is important and also interesting to notice the result of the award of these prizes for the best milkers which was arrived at on Friday the 29th ultimo, and which we extract from the *Agricultural Gazette*. "The trials being for quantity yielded per cow per day of twenty-four hours, with a comparison of the quality of the milk as determined by Dr. Voeleker's analysis. The first-prize Shorthorn cow "Daisy," being one of a pair which received the first prize in the second class of Shorthorned cows, shown in pairs (and not eligible for "Herd Book"), exhibited by the West London Dairy Society. This cow "Daisy," gave in two milkings in twenty-four hours 48½ lbs. weight of milk of very high quality, which latter merit carried the first prize. Mr. George Taylor's cow "Beauty," which obtained the second prize in the third class for Shorthorns, shown singly, and not eligible for the "Herd Book," yielded a still greater quantity—namely, 50½ lbs. of milk, but of quality somewhat below that of the other, thus lowering her to the second place. The first-prize Dutch cow gave 40½ lbs. of milk of good quality; and the second-prize Dutch cow 43½ lbs. of a lower quality. The first-prize Ayrshire gave 25½ lbs. of milk; and the best Jersey 30¼ lbs. of milk. The rich quality

of the Jerseys and Guernseys, however, was so superior as to require a second analysis before the comparative merits of the competing cows could be determined." We hope to give the actual result in our next communication.

In Class 4, Ayrshires were only remarkable for the large entry by one exhibitor, who received all the prizes in this class. As, however, there was nothing requiring special notice relating to these cows, we shall refer the reader to the small quantity of milk just stated, as given by the one competing for the milking prize, which is not likely to give this breed any preference, except as hardy animals capable of withstanding an inferior climate, and yielding a fair quantity of milk whilst feeding upon herbage of inferior quality growing upon the moorland and mountains.

Class 5, Jerseys.—This breed of cattle is, we may say, next to the Shorthorns as dairy stock; in fact, in some situations they are superior in some respects, yet really they each possess a local standing, and both deserve it when it is considered the different climate and soils upon which they are kept, and the different circumstances by which they are attached to certain districts. We shall, however, consider more fully the points connected with the Jersey breed as dairy cows when we get Dr. Voelcker's returns of the quality of their milk as compared with other breeds. The show of Jerseys was, as might have been expected, very extensive, the first and second prize being awarded to Mr. George Simpson of Wray Park, Reigate, Surrey, who has now been celebrated as an exhibitor of Jerseys for many years, and he as yet maintains the first position in the kingdom as a breeder of Jersey cattle. There is, however, another breeder who was not far behind him, who took the third prize in this class of cows—namely, Mr. John Carders of Town Hill, Westend, Southampton, who exhibited two beautiful animals. The stock of either of these two competitors can be highly recommended to the notice of noblemen and gentlemen as possessing animals well calculated for the ornament of the park and pasture lands, and at the same time capable of yielding not only profit, but butter of the finest quality and colour. We propose next week to call attention to the Guernsey breed as dairy stock, and also other breeds, such as the Kerry and the cross-breeds, with a review of the practice of cross-breeding, &c.

(To be continued.)

WORK ON THE HOME FARM.

Horse Labour.—There has been serious hindrance to the horse labour of the farm lately, and there is but little Wheat sown; therefore this work must now be urged forward at any and every opportunity. Whilst we write the weather has become fine, and the land, all but the strongest flat-lying soils, is in good condition, the work should proceed without further delay. However, the weather cannot be trusted in November, which is the best month for sowing Wheat upon dry healthy land in a favourable climate; therefore the home farmer should not set out more seeding than can be done in a day, so that any sudden change to rain may not interfere with the finishing work. This, however, applies to the land which has laid previously ploughed. Upon the root land, however, where the sheep have recently fed off the crop, the land should be ploughed and sown simultaneously and none left unfinished in the evening, because the weather peculiar to this month is rain and frost by turns, or in succession, either of which will cause great delay unless the land is finished off as fast as sown. On some of the hill farms, either on the stone brash or chalk, the sowing of the lea ground is completed. The horses will in consequence be at liberty to return to the autumn fallows for the most part lying in an unfinished state. A few more fine days will enable the Howard's patent lifting drag to be used for combing out and loosening the heaps of couch and weeds, which the late rains have settled down so close that they cannot be collected with either the chain harrow or horse rake without being moved again. Where the land is clean the Wheat stubbles, &c., can be now deeply ploughed and allowed to lie during the winter months, and if the land is free from couch it will require no more ploughing in the spring. It may be made a perfect tilth by the action of the scarifier, lifting drag, &c., and prove in excellent condition for seeding the root crops, also Barley at the earliest period. We ask the home farmer to remember the number of fields last spring which were ploughed several times, and at the seed time the weather proved so dry that the Mangold seed vegetated most irregularly, and the crop is deficient in consequence. This is so often the case that whether the season proves wet or dry the land which requires no ploughing in the spring is sure to be in the best condition for sowing early with either Barley or root crops.

Hand Labour.—Work peculiar to the winter months will now prevail, but that which must be done first is the pulling and storing roots in the field by pitting and covering them with earth. The Swedes which will be required for the sheep during winter and spring, for those which are pitted in good condition are always better for sheep than those which have been left in the land, as either the action of frost or the production of new roots depreciates the feeding value. The major portion of the Mangold crop has been carted off the land and heaped or stored away for use. When grown within

reach of the seashore the ordinary seaweed is the best covering for the heap, as it affords better protection from frost than any other material, and requires less earth on the outside of the heap. Most of the stock fairs for sheep have been shortly supplied, and although sheep have maintained full prices yet they would have been still higher had the price of corn been more remunerative, as there is one of the best root crops on all soils we can ever remember. Shepherds must not give their in-lamb ewes too many roots, and a fair allowance of hay will be more than ever necessary. Unfortunately a large portion of the field hay has been very much damaged, but where the substances used for flavouring were added to the hay when being stacked it is found that sheep eat it much better, being attracted by the aroma imparted to the hay. Fattening sheep have made good progress lately upon all dry land, but the quality of the hay being deficient much more cake than usual has been used for feeding, about a pound per sheep per day being considered a fair allowance. Cattle in the boxes have capital roots to thrive upon, but these will require, if used for fattening cattle, not less than 4 lbs. of cake in meal with 2 lbs. of bean or barley meal added for each animal per day, and strewed over the cut roots at feeding time. Cut straw will then be sufficient without hay, and a moderate quantity of roots, not exceeding 56 or 60 lbs. per day each, according to the size of the animals. The horned Dorset and Somerset ewes are lambing fast, with many twins in a healthy state, but more lambs than usual will this year fall in the month of November, and it is the best month for lambs to come intended for the general early trade in the metropolitan market, as well-fed lambs will be ready to kill at twelve weeks old.

REPORT OF THE PROCEEDINGS OF THE POULTRY CLUB—OCTOBER, 1880.

WE desire, as your Committee, to lay before you some account of the proceedings of the Poultry Club from the date of our last report up to the present time. Your Committee has since then met ten times. You will remember that in that report we recounted the steps which we had thought it necessary to take during the previous year for the suppression of trimming and dishonourable practices in the exhibition of poultry; these included the permanent or temporary disqualification of several exhibitors from showing at all shows held under the Club rules. We are now glad to inform you that, as far as we are able to judge both from our personal experience and from the reports of some of the most competent poultry judges, these steps have had a very marked effect in suppressing trimming and promoting honourable competition. During the past year we have in no single instance had the unpleasant necessity of disqualifying any exhibitor; and the late Mr. E. Hewitt, whose loss we all deplore, stated after judging at the last Crystal Palace Show that he believed there had never been a great exhibition at which the birds were more honestly shown; he likewise in a letter addressed not long before his death to the Honorary Secretary of the Club warmly eulogised the course it had pursued, which in his opinion had much contributed to this desirable change. Since our last report about a dozen shows have been held directly under the rules of the Club. In many other schedules the most important clauses of them have been adopted; indeed hardly a schedule can now be found in which the rules against dishonourable practices are not worded with far greater precision and stringency than they were at the time of the Club's formation.

The Club has of late been applied to in several cases to give pecuniary aid by guarantee or otherwise to shows held under its auspices, and we have thought that the state of its finances justified our acceding to these requests. As many such seem likely to be made we have appointed a sub-Committee consisting of Messrs. A. Darby, E. Pritchard, and the Rev. W. Serjeantson to consider and advise upon all such applications. In our last report we gave our opinion that before long the Club would be in a position to undertake the management of a large exhibition. Communications received from many members led us to believe that there was a general wish that this should be done. Last April an opportunity seemed to present itself. The Council of the British Dairy Farmers' Association opened a negotiation with us with a view to our undertaking the entire management of the Poultry and Pigeon Show to be held in October in the Agricultural Hall. A long correspondence ensued between the Secretary of the British Dairy Farmers' Association and the Honorary Secretary of the Club, which ended in a definite offer being made by the Association to the Club. A special Committee meeting was held on May 24th at Oxford to consider this and other pressing matters; but when it was found that the dates of this proposed Show and that of the Oxford Show clashed the following resolution was passed—"The Committee having considered the offer of the British Dairy Farmers' Association that they should undertake the management of their Poultry Show, regret that they are unable to do so. Had the Show been held at any other date than that always fixed for Oxford their decision might have been otherwise; but they think that Oxford deserves too well of poultry fanciers to justify them in undertaking a Show which must injure its prospects."

We regret that circumstances prevented the carrying-out of a scheme, which, but for this unfortunate fixture would, we believe, have given general satisfaction to the Club, but expect to be able almost immediately to announce that arrangements have been made for holding a show in January under the management of the Club. For some time past the labours of your Committee have been

constantly on the increase from the number of disputes among fanciers which are submitted to their arbitration. The fact that they are so submitted, and that, too, sometimes by fanciers who are not members of the Club, is naturally gratifying to your Committee. To publish any list or details of them would be obviously inexpedient. In the majority of cases prompt settlements or arrangements are effected through the intervention of the Club, and ready acquiescence has been given by both sides to its decisions. In one case unfortunately this has not been the result, and a dispute has been dragged into publicity: we allude to the controversy arising from the Hemel Hempstead incubator contest. We do not wish to reopen the question, but as garbled accounts of our action and decision have appeared in print, we inform you very simply what we decided and what we declined to decide in the matter. In the charges submitted to us two points seemed much confused—viz., imputations against the general management of the contest, and imputations against more than one member of our Club in some way connected with the contest. We endeavoured to separate the two, and concerning the latter entirely exonerated the gentlemen in question; concerning the former, from the many contradictions in the statements of the two parties, and our want of power to examine witnesses on oath, we refused to give judgment.

Other important questions have from time to time been brought before us, especially that of a new standard of excellence for poultry, which we consider rather subjects for discussion at a general meeting than matters to be decided by a Committee. We shall therefore endeavour to have them brought forward at the general meeting during the Crystal Palace Show, when we trust to see a large number of the members of the Club and other fanciers.

POULTRY CLUB MEETINGS AT THE CRYSTAL PALACE.

MAY I announce through your columns the arrangements for the meetings of the Poultry Club during the Crystal Palace Show? The first committee meeting will be held in my room at the Crystal Palace Hotel at 5 P.M. on Monday the 15th inst. The general meeting will be held at 4 P.M. in a room adjoining the Marble Hall in the Palace. This room is near the entrance to the Palace from the low level station. As on a former occasion the Marble Hall was found intolerably cold, I may mention that the room will be warmed. To this meeting all fanciers, both ladies and gentlemen, are invited, and questions of much interest will be discussed, and the undermentioned resolutions will be submitted.
—O. ERNEST CRESSWELL, *Hon. Sec.*

RESOLUTIONS.

To be proposed by Mr. A. Comyns. To be seconded by Mr. O. E. Cresswell:—

That the following be added to the rules of the Club:—

"That, except as hereinafter provided, every candidate for election as an officer or committeeman shall be nominated with his own consent by at least two members of the Club; that notice in writing of such nomination be sent to the Secretary at least a fortnight before the election, and that a list of the names and nominators of such candidates be furnished to each member with his voting paper; that retiring officers and committeemen who have not signified their unwillingness to serve again be eligible for re-election without nomination, and that the number of votes obtained by each candidate be published after the election."

To be proposed by Mr. A. Comyns:—

"That a copy of the rules of the Club, with a circular specially directing attention to the objects thereof, be sent to each person whose name appears in the poultry section of the 'Fancier's Directory' for 1880."

To be proposed by Mr. S. Lucas. To be seconded by Mr. A. Comyns:—

"That a circular be sent to the secretaries of the various poultry shows in United Kingdom requesting them to communicate with the Secretary of the Club as early as possible as to the dates of their shows in the season 1881-2, with a view to ascertain if, and how far, any of such shows are likely to clash, and, if possible, to obviate such clashing."

To be proposed by Mr. L. C. C. R. Norris. To be seconded by Mr. A. Comyns:—

"That a circular be sent to the principal railway companies throughout the kingdom directing their attention to the various abuses existing as to cost of carriage, rough handling of birds, and other similar points, and requesting the application of remedial measures."

To be proposed by Mr. A. Comyns. To be seconded by Mr. E. Pritchard:—

"That the Committee be requested to formulate a scheme for the increase of the number of the Committee by the addition of sufficient leading fanciers in London and the other important local centres of the fancy, to allow of the formation of a quorum for the transaction of the business of the Club in each local centre. The Committee be empowered to form sub-committees of its own members, and to delegate to such sub-committees the power of deciding any question or cases which it may think fit. That the Committee be empowered

from time to time during the year 1881 for the purpose aforesaid to order that the number of the Committee be increased. That any new members to be added to the Committee be elected in the usual way by the Club."

To be proposed by Mr. H. J. Storer:—

"That in the opinion of this meeting it is desirable, when the funds of the Club will admit thereof, that a club room be hired in London for the use of members at least one night in each week."

To be proposed by Mr. O. E. Cresswell. To be seconded by Mr. A. Comyns:—

"That in the opinion of this meeting it is desirable that a standard of excellence be prepared by the Committee."

To be proposed by Mr. E. Pritchard. To be seconded by Mr. L. C. C. R. Norris:—

"That in the opinion of this meeting it is desirable that a Club Show in London, or some other large town be held in the autumn of 1881."

Question to be asked by Mr. A. Comyns:—

How many committee meetings have been held during the past year, and how many of such meetings have been attended by each member of the Committee?

VARIETIES.

THE GOVERNMENT AND IRISH FARMERS.—At a recent meeting of the Kildysart Board of Guardians, a communication was read from the Local Government Board consenting to the postponement for twelve months of the payment of the first instalment of money advanced for the purchase of Potatoes and Oats, under the Seeds Act, during last spring. The farmers are highly pleased at this concession.

— ENTOMOLOGICAL SOCIETY.—At the last monthly meeting of the Entomological Society Sir John Lubbock exhibited some interesting larvæ, which Mr. Calvert had forwarded to him from the Troad, through Sir J. Hooker. These larvæ have recently appeared there in great numbers, and are likely to prove most useful, as they feed on the eggs of locusts. Sir John Lubbock thinks that they are coleopterous, and probably those of a beetle belonging to the same family as the Cantharis or Blister beetle. Mr. Riley has recently described the transformations of certain insects belonging to this group, and natives of the United States. The young larvæ when they leave the egg are thin active little creatures, which eat their way into the cases or "pods" (as they are called from their shape) of locusts' eggs, where they rapidly grow into flat fleshy grubs. Mr. Calvert states that in his neighbourhood a large proportion of the locusts' eggs have this year been destroyed by these larvæ. If the species does not exist in Cyprus it might be well worth while to introduce it there.

— THE ROYAL AGRICULTURAL SOCIETY.—At the meeting held on the 3rd inst., at which the Prince of Wales and an influential company were present, it was decided, on the recommendation of the Implement Committee, to offer a gold and silver medal for the sheaf-binding machines which, after a trial during the harvest of 1881, the judges consider the best and second best, the binding material to be other than wire. Letters were read from the Secretary of State for Foreign Affairs respecting a national convention of sheep husbandry at Philadelphia, and an international sheep show at Mecklenburg. A letter was read from the Countess A. de Noailles, offering a prize of £20 for an essay on the benefit to flocks and herds which would accrue from giving them access to running water to drink in place of stagnant ponds, and it was resolved to accept this offer. Reports of various standing committees were received and adopted. A discussion took place with reference to the importation of cattle from Ireland affected with pleuro-pneumonia; and on the motion of Mr. Bent, seconded by Mr. Wakefield, it was resolved "that the President of the Society be requested to call the attention of the Privy Council to the letter received from the Clerk of the Peace of the County of Cumberland relative to an outbreak of pleuro-pneumonia which occurred in a cargo of cattle lately landed at Shilloth, and that he should urge upon the Privy Council that more stringent regulations and more careful inspection of imported Irish cattle is requisite both at the ports of embarkation and arrival."

— BEES AND CLOVER.—Bees are necessary to the fertilisation of some kinds of Clover. This fact the New Zealand Government have discovered to their great dismay, for the Dutch Clover in that colony will not produce sufficient seed owing to the absence of the

particular bee necessary to fertilise it. Again, it has been found that twenty heads of Dutch Clover yielded 2290 seeds; but twenty other heads, protected from bees, yielded none. In like manner, a hundred heads of Red Clover produced 2700 seeds, but the same number protected from the visits of insects were all sterile. Hence it may be logically inferred that as no other insects visit the Clover, were the humble-bee to become extinct in England the plant which is dependant upon it for existence would either become extinct or at least comparatively rare.—(*"Flowers and Insects," in "Science for All" for November.*)

— **ACORN POISONING.**—We draw the attention of our readers to the dangers which beset cattle at this period of the year, when, as now, acorns are being scattered over the pastures in bushels, and young stock are still at large. During the past summer the Oak has produced an immense crop of fruit, so much so in some instances as to bend and even break down huge branches from their trunks. It will be remembered by some at whose expense our experience of acorn poisoning was acquired that in 1868 and 1870, and on several subsequent occasions, large numbers of cattle succumbed to the poisonous effects of Oak "mast," and many more were so far emaciated and otherwise damaged by disease as to require much time and costly care to restore them to a thriving state. Moreover, dairy farmers sustained serious losses, not only in the diminished supply of milk which followed the unrestrained use of acorns, but also in the wholesale sinking or abortions which the same cause provoked. When well harvested and properly served out, acorns constitute a useful article of diet for all kinds of stock, and, with ordinary care, no ill consequences should follow their use. It is more especially the fresh unripe fruit in which the noxious principle predominates; hence acorn poisoning is most prevalent early in the season, when sharp frosts and strong winds have dislodged them from the trees before maturity has been reached. Besides the astringent and poisonous acid contained in acorns, there is also the indigestible husk, or shell, which renders their too free use perilous to stock at all times. When it is remembered that nearly 50 per cent. of animals attacked with this disease succumb to its effects, the present luxuriant crop of acorns may be contemplated with fear as well as with profit. To be forewarned is to be forearmed, and if reasonable precautions are exercised at once no loss need be suffered. The removal of the offending agent is all that is required. Itinerant gatherers should be encouraged, where acorns abound, or boys told off specially to pick up the fruit as it falls. Young stock being most susceptible of acorn disease should not be allowed in the pasture until the bulk of the mast has been removed.—(*Agricultural Gazette.*)

— **CASELL'S MAGAZINE OF ART.**—Messrs. Cassell & Co. have sent us the first part of this work of which it is scarcely possible to speak too highly. It is of large quarto size, contains forty-eight pages of engravings and letterpress, the paper, type, and engravings being of excellent quality. The frontispiece is an admirable etching of Erskine Nicol's painting "The Trio." One shilling is unquestionably a moderate price for such a fine production as this undoubtedly is.

NEW AND OLD PRACTICES IN BEE-KEEPING.—No. 3.

CAREFUL investigation leads to discovery in many instances, and in bee-keeping new ideas are obtained and new practices introduced. Let us examine and compare two.

One is the practice of utilising old comb, of cutting it out of one hive and fixing it in another. Of late years this practice has been strongly recommended by one of our schools. The teaching in support of this practice is to the effect that if old combs be given to bees and fixed in their hives, they will be saved the trouble and expense of wasting honey for material or wax to build fresh combs. This is very plausible teaching and reasoning, for it is well known that new combs are costly, both to bees and bee-masters, in their erection. The task that a swarm of bees imposes upon itself on entering a large hive, filling it with combs, brood, and honey, is not a small one. The labour of the task is prodigious, but they willingly undertake the work and carry it out, weather permitting. The question for discussion is, Would old combs assist the bees? If their hive were filled or half filled with pieces of second-hand combs, would the bees thrive better and gather more honey, or rather store up more? This is an important question, deserving the careful attention of all earnest bee-keepers.

I disapprove of the use of old combs, especially of artificially refixing them in other hives after removal from their own. Such refixtures are greater hindrances than helps. In some few instances the combs of swarms that perish in winter may be profitably used by putting swarms amongst them on the following season. Even such young combs as these I should not remove for refixing.

The other modern practice which I have alluded to is quite the reverse of this—viz., the destruction of combs while they are comparatively young. Both profit and health are at the bottom of this practice. I follow and recommend it in great harvests and honey seasons. Why? Because in such seasons the yield of honey is very great, and stocks made of two swarms united and sugar-fed are cheaper and better than heavy honey stocks. Mr. Edward Thorp of Sale adopts this practice. He is an amateur, and of course keeps bees for pleasure, but he manages them well and profitably. His stock is reduced to two hives. Last spring or summer he sold one swarm for 20s., the other five were kept for honey. All their combs were destroyed in September, and in their destruction they yielded 105 lbs. of honey and honeycomb. The run honey was sold for 1s. 3d. per pound, and the comb for 1s. 6d. per pound. The bees of the five hives are now being fed into three stocks by giving them 72 lbs. of sugar made into syrup. One of the stocks will be sold, which, doubtless, will realise more than the cost of the 72 lbs. of sugar divided amongst the three. We see that by Mr. Thorp's mode of multiplying his stocks in summer and destroying their combs in autumn, his income from two stocks (originally) is more than £7. I know not what his expenses were in spring-feeding and in sending his hives in August to the moors; but, considering the season of 1880, I estimate that one swarm sold and 105 lbs. of honey obtained is a good return from two stock hives. Besides, by following this practice year after year Mr. Thorp will never have foul brood in his own apiary. I ask the reader to ponder on his example and success, and compare results.

Many collateral points claim attention when the question of comb-building and comb-destruction are considered. On the question of swarming and non-swarming, of supering and non-supering, there is great diversity of opinion and practice among apiarians. All, or almost all, have some reason on their side. In some districts there is no Heather, honey-gathering ends with July, and the bee-keepers there naturally do not want swarms to waste their time in building combs that are never filled, but adopt the non-swarming and supering system. Others who have had abundance of super honey during a favourable season may think they have found out the real secret of success. Such earnestness is pleasing, but it is well to temper zeal with wisdom and experience. How are old black combs to be disposed of, and when? How are the young sweet combs to be obtained, and when? In the absence of swarming, where do young queens come from? These points are not forgotten in well-managed apiaries, and practices are modified to suit seasons and circumstances. But it should be borne in mind that the wax in supers is as costly as the wax in swarm hives. The question is, How to obtain most honey or profit? My prejudices are based on experience and success, and year after year they grow stronger and stronger in favour of the old practice of swarming. This system I prefer for both honey and honeycomb, and the reason for it is this: On the swarming system of management the bee-master has always plenty of bees in autumn to make his hives doubly and trebly strong. Autumnal unions of swarms make hives strong for work of all kinds, and this is the secret of success in all apiaries. Being now unequal to garden work I am trying to sell my place. If it be sold I will devote my time to keeping bees and manage them on the swarming principle.—A. PETTIGREW.

PROTECTING BEES—PRODUCTS OF BAR-FRAME HIVE.

It will not do for us to put our bees in houses the same as the Americans do, but above all things we must keep them warm. If they are well wrapped up in hay and well ventilated there is no fear of their sustaining injury. I have eighteen stocks placed in winter quarters; they are wrapped in hay. A board is put up in front to keep the sun from shining too early on the mouth of the hives. In the event of snow I shall place the board straight in front to protect the mouth from the reflection of the sun when shining on the snow, which often brings the bees out only to fall down and never return. This board is a great saving to the bees, and it should be put up now.

I have taken up all my Crocuses, and put them in boxes to have them in bloom early, so as to afford pollen for early breeding.

I have read the article in the *Journal of Horticulture* on the

great harvest of honey at Carluke. I suppose the Carluke men would weigh the straw skeps along with their honey and perhaps their floorboards, so that would bring the yield down a little, say six skeps at 7 lbs. each would be 42 lbs., which deducted from 474 would leave 432, and if they weighed the floorboards they would average 6 lbs. each; that would be 36 lbs., leaving a nett weight of honey 396 lbs. More than this can be realised from the bar-frames if you give them room and extract Clover honey in its season. I had not my extractor in time this year, else I should have had a better turn-out of honey. There is no mistake but their hives were good; but what would their honey look beside good squares of honeycomb that could be sent all over the world without packing? and another very important point—we can have our honey in the market early. I had some for sale in June. We can supply all the markets with honey before they would take theirs to the Heather, and I have no doubt that the time will come when they will have to give up their straw skeps for this reason—that they will not find a market for honey. For instance, in Dalbeattie we had all the people supplied with honey before the Pettigrews with their straw hives could come in with their produce. When they did come they could not sell it, and were offering it at 2s. 3d. per quart. How does this look alongside 3s. and 3s. 6d. per quart, which I readily obtain?

After reading the article about the Carluke bee-keepers I looked up my book to see if I could find a yield anything like that recorded, and I send what I have found. Mr. Pettigrew will find some good hives about Dundee; at least from what I hear at Kelso, I should not be surprised to see them sending in records of 200 lbs. out of one bar-frame hive, not saying anything about swarming. Mr. Steele of Dundee told me he could make £6 of every hive he has in his apiary—that is, £2 a year more than any of the Carluke men obtain.

I will now give you the account of my hive, but I wish to say they were not all like this one, as I had neither honey nor swarms from one. The reason of this was a bad queen, but I gave the bees one, so expect better results next season; the rest did very fairly. There was one or two at the end of the season that after working well did not kill their drones; this means queenlessness, so I gave them queens, and the next day they drove out their drones. On the 16th of May I put on twenty-four sections, supers, and on the 16th of June I had a swarm of this stock, so that I had to take off the supers; there were fifteen of them, weight 1 lb. each. On the 24th June it gave a cast or second swarm, equal to many first swarms, and on the 1st July it gave a third, which I returned after taking the queen from them; I then put on supers to nearly the end of the season, when the amount of super honey was 50 lbs. I then turned up the box and cut out 16 lbs., and now it weighs 54 lbs. The total weight from the old stock not including wood would be 120 lbs., then the swarm from the above hive worked very well, and before the Heather honey came in I extracted 30 lbs. from the combs. I returned them and had them refilled in sixteen days; I put on supers, and at the end of the season I had taken 69 lbs., and the frame that was refilled with Heather honey that could not be extracted with the extractor weighed 34 lbs.; the total for this swarm was 135 lbs. The cast or second swarm was only eight days behind the first, and gave 61 lbs. in supers and 62 lbs. in stock hives, it has now 10 lbs. of honey and 20 lbs. of sugar for the winter. Total weight of honey in the second swarm will be 133 lbs., so the grand total will be—old stock, 120 lbs.; first swarm, 135; second swarm, 133; total, 388. This does not include frames or supers, only the honey that came out of them.—J. THOMSON.

BEES AND HEATHER.

THE report of Mr. Pettigrew, published last week, of the successful bee-keeping of Mr. Lindsay, has made some of us mid-country apiarists quite jealous. Our pasturage here is chiefly white Clover, and this season as soon as that was ready rain fell nearly every day until the Clover was over, so that a surplus with us, only in exceptional cases, is quite out of the question. I have been thinking if we could take, say, six or eight stocks to the Heather for a fortnight in a fair average season, and have our usual ten or fourteen days' holiday with the bees, they would if the weather were at all favourable not only pay our holiday expenses, but leave a handsome profit besides. When Mr. Pettigrew finds time I hope he will give us his opinion about this, and also direct us to the nearest fields of Heather.—C. F., *Leicester*.

OUR LETTER BOX.

Pigeons for Table (*E. C. O.*).—The smaller Runts are excellent for the table. We say "smaller," because the present exhibition Runts are too large to

breed well and are bad parents. Archangels, too, are excellent breeders and good birds for eating, and have the additional merit which Runts have not, of being very active, and so escaping from cats and other enemies. It is a good time of year for establishing whichever kind you may choose.

Doves Unhealthy (*Idem*).—The probable causes of your young Doves being weak in legs are either in-breeding or the parents not being supplied with sufficient bone-making and digestive food. Give them plenty of road grit and old mortar broken up. If you have bred much from the same stock procure some fresh birds from another strain and cross them with your own. We have seldom in our own aviary had young Doves suffer in the manner you describe, but we once gave away a related pair, the produce of which were again in-bred, and the result was leg-weakness and paralysis in nearly all the young birds.

Canaries Afflicted (*Mrs. Brettingham, Colchester*).—Your hen Canaries certainly are in a very sad condition, and there are but little hopes of your keeping them alive for breeding with next season. It is a very bad sign when they become so ruffled in feathers, roost upon both legs, and fall off in their appetites. The birds have become affected over their moulting. They do better with plenty of room for exercise and water to bathe in over their moulting, which has a beneficial effect during the casting of old and the pushing out of their new feathers. The discoloured veins and appearance of their stomachs show signs of inflammation, and unless they are removed into a warmer temperature they will speedily die. Hold the birds over a vapour bath for three or four minutes, and the moisture and warmth will ease their bowels. Give to each one drop of castor oil, and likewise rub their stomachs and vents gently with a little of the oil on the end of your finger or with a small camel's-hair brush. Supply a bread and milk diet, in which mix a couple of grains of magnesia. If the birds become somewhat convalescent after the above treatment add to their drinking fountain a few drops of brandy, and keep them free from draughts.

Bees in Winter (*Busy*).—The doors of the hives should be contracted to keep out mice except when snow is on the ground. In cold and severe weather bees do not come out; in mild winter weather they leave their hives about mid-day for exercise and for purposes of cleanliness, and these occasional winter flights are good for them. If the doors of hives are kept closed all winter much harm is done and many lives lost by the bees struggling to get out in mild weather. If kept by bad weather or closed doors for many weeks together in their hives there are heaps of dirt and dead bees formed inside, which are disagreeable to creatures so sensitive of smell as bees. Your house is a good protection to your hives. Let the small holes in front be large enough to enable the bees to carry their dead out, and place some soft hay round the hives to keep the bees comfortably warm in winter.

REMARKS.

- 31st.—White frost in morning; cold bright day and windy.
 1st.—Fair, but overcast throughout.
 2nd.—Thick white frost, very cold morning, fine day, with bright sunshine in forenoon.
 3rd.—Cold day, with very bright sunshine and much wind; aurora 8.25 P.M.; bright starlight night.
 4th.—Fine with bright sunshine; foggy between 5 and 6 P.M.; clear starlight evening.
 5th.—Thick fog in morning; milder day; much cloud.
 6th.—Slight fog in morning; mild day, and fine, with sunshine from noon till 3 P.M.

Generally cold and dry, with high barometer.—G. J. SYMONS.

COVENT GARDEN MARKET.—NOVEMBER 10.

TRADE keeps very quiet. Consignments of Apples from America and Canada continue. Home-grown fruit is now beginning to fall off in supply, the bulk of the crop having changed hands.

LILY OF THE VALLEY.

IT is questionable if any other flower is so generally popular as the Lily of the Valley. No other possesses such delicate charms, none is more useful, and none so much sought after by all classes, the Rose excepted. The flowers are doubly welcome when they are produced months before their ordinary time, which can be accomplished with ease and certainty if a proper system of cultivation is followed, and these notes are intended to show that a succession of Lilies of the Valley can be maintained for seven or eight months. The length of time the outside supply lasts depends upon the situation the plants occupy, and upon the season. To maintain a supply from the commencement of the new year is by no means difficult, as imported single crowns and clumps from the Continent can be had in flower in abundance during January, and by hard forcing flowers may be obtained by Christmas. On more than one occasion newly imported plants have been introduced into strong heat here as soon as they arrived, but they did not start for months afterwards, and some of the plants produced their flowers the following July and August outside. This is sufficient proof that the Lily of the Valley cannot be forced until it has received a thorough rest. How can these imported plants be expected to bear flowers nearly as soon as they arrive? They are taken up as soon as they show signs of rest, and many of the leaves are upon the plants when they arrive prematurely ripened by the journey. It is unreasonable to suppose that plants receiving scarcely any rest will start satisfactorily and produce good flowers by subjecting them to the strong heat of forcing houses.

For some years past I have carefully read the various gardening periodicals, and I do not remember seeing any statement of these flowers being produced at the beginning of November until I recorded the fact in the *Journal of Horticulture* in 1878. They can even be produced by the last week in October if an effort is made to have them thus early without adopting extreme measures in forcing. Imported roots will not produce flowers during November, and to accomplish this plants must be grown in pots and assisted after flowering to make an early growth so as to receive an early rest. If a number of imported clumps or strong home-grown plants from the border are potted in good loam, a seventh of manure and sand, and forced after the new year, the foliage can be had with the flowers, which is essential to the plants if they are to produce their flowers again in early autumn. Some little care

must be taken that these plants are not seriously checked while flowering, nor must they be placed outside or in cold frames and neglected after flowering, which is frequently the case. A vinery or warm Peach house is suitable, and a light position should be afforded the plants until growth is completed and matured. They can then be placed outside in a sunny position to thoroughly ripen their crowns, which must not, however, be done by withholding water to induce premature rest. Liberal feeding should be resorted to while the plants are growing and until the growth is completed, the crowns plump, and the foliage becoming yellow. They should not suffer through insufficient supplies of water during any stage, and after the foliage has fallen the plants can remain outside resting until they are required for forcing; but they must not be allowed to become dust dry at any time.

After the plants have had a good rest forcing can be conducted without trouble. This season plants so treated were plunged into tan, the crowns being placed about 2 inches below the surface, and the bottom heat ranged at about 85°, scarcely ever varying, and the flower sprays quickly appeared and were gathered here on the 3rd of the present month. As soon as the flowers appear through the tan it is removed from around the crowns and inverted flower pots are placed over them, stopping-up the hole in the pot for a few days. This assists in drawing the flowers well up, which should afterwards be gradually exposed to the light, and they will increase in size, substance, and fragrance.

This system of early forcing will year by year spoil some of the plants, so that an annual preparation of a number is needed. When the flowers come first the foliage afterwards is naturally weak. These early-forced plants must be carefully hardened, and when frost is past plant them outside where they can remain for two years to thoroughly recover their strength, and a number of plants forced after the new year should again be grown on for the following autumn. Plants from the outside when well established can be lifted, and either placed in pots forced upon beds of leaves or laid upon vinery borders, and a little soil scattered amongst them until their flowers are produced. It is a good plan to place the roots in shallow boxes in vineries afterwards; they are much more readily removed to harden off again before planting out. By introducing them in boxes for cutting, potting-up a quantity in pots and introducing them in batches, it is easy to maintain a succession until flowers can be had outside. Lily of the Valley will succeed in pots for a number of years providing the drainage is kept good, the plants not subjected to too early forcing, and being well supplied with liquid manure while growing, so as to produce stout foliage, which is the precursor of bold crowns.

To have a good supply of these flowers outside as long as possible, it is necessary to plant in different aspects, some in a sunny position, others again to succeed them, and for the last supply plant in a northern aspect. The ground should be liberally manured, and in autumn after the foliage has faded some short decayed manure may be thinly spread amongst the plants with much benefit to them the following season. During dry weather a good soaking of water may be given, and occasional supplies of liquid manure. The outdoor treatment is very simple, and it is easy to prepare a few plants annually in Peach houses or vineries to supply early flowers through

November and December ; after that period the production of flowers is comparatively easy.—WM. BARDNEY.

APPLE AND PEAR TREES WHICH CANKER AND WHICH DO NOT CANKER.

It may, perhaps, serve a useful purpose for me to give a list of the Apple and Pear trees which I find either are apt to canker, or which are free from that injuring and deforming disease. The time of planting is again upon us with its pleasures and hopes. I say pleasures, for I own to feeling very pleased when I receive my annual bundle of young trees. I undo them in a flutter, and examine each, its growth, its shape, its size. I always assist at the planting itself, seeing that my man plants and not buries, and that he treats the tender infants with every care, avoiding all rough usage. I own to having pleasure when I see a new comer safely and uprightly in the soil. There is, however, the future to think of. Will the tree grow, fruit well, and will it be free from disease? Of diseases I will now speak only of canker. My soil and climate are good ; the former loam on a sandy clay, the latter that of the Bath district, and my garden is on a south-west slope and well drained ; yet some trees canker and some are wholly free from this disease.

Side by side stand a Dumelow's Seedling and a Striped Beeding. The first is perfectly healthy, the second badly cankered. I would say as to Dumelow or Wellington I do not know its equal in all respects, and think better of it each year. Worcester Pearmain free from canker, Beauty of Kent dies of it. Loddington Seedling perfectly healthy, Joaneting cankers a little. Lord Suffield free, so Duchess of Oldenburgh, but not entirely free is Margaret. Irish Peach, best of all summer dessert Apples in every respect, is perfectly healthy. Emperor Alexander, Cox's Orange Pippin, Summer Golden Pippin, New Hawthornden, healthy ; while Cox's Pomona, Golden Pippin, and Betty Gecson all canker slightly, the Pomona the worst. Lewis's Incomparable free, so also Gravenstein, but not quite free Sturmer Pippin. Annie Elizabeth healthy, while old Hawthornden cankers worst of all. Yet who would be without it? I find it lasts and fruits well about twenty years and then dies of canker. Keswick Codlin, Ecklinville Seedling, Warner's King, and Stirling Castle all free. I consider Ecklinville Seedling one of the best possible Apples—hardly eleven others equal to it. Stirling Castle is a charming little fellow, bearing almost too abundantly, but is a picture in blossom and with fruit. Gooseberry Pippin cankers badly, so Cellini, but not so Peasgood's Nonsuch, Tower of Glammis, and Bedfordshire Foundling.

Next I come to Pears, and how much I wish that people would not overpraise so many varieties of these fruits. I sometimes think that writers pen their commending descriptions in France or Jersey and not in England. I only know of one Pear—the Jargonelle—which can scarcely be overpraised. It is exactly like the Gloire de Dijon among Roses. As there may be and are Roses of better shape and finer colour, yet "all round" none equals "old Glory." So of the Jargonelle Pear. It grows magnificently, it fruits regularly and abundantly, and knows not disease ; it suits all climates and all tastes. There are indeed finer-flavoured Pears and more delicate to the palate, but all round none equals the old Jargonelle. In five and twenty years I have never known it fail, and by gathering its fruit at various times I make it last quite a month for the table, and have also a large number stewed, and none are better for that purpose. Next in order happens to come Williams' Bon Chrétien, a shy, very shy, bearer with me, and somewhat inclined to canker. This and the further-named are all pyramids, Jargonelle only on a high, very high, wall. Seckle cankers badly, and I break off branch after branch. I think it a Pear not worth growing ; with me the fruit is small and poor. Soldat Esperen, or Soldat Labreur I think well of ; its growths Poplar-like and pleasing : it does not canker, it fruits regularly, and with artificial heat ripens well. Beurré Hardy is also perfectly healthy. Beurré Diel cankers slightly, not so Beurré d'Amanlis. Winter Nelis utterly fails with me as a pyramid, while Bergamotte Esperen answers perfectly—a healthy variety ; it crops regularly, and the fruit if put in a box near a stove ripens well, and is of delicious flavour. With Summer Doyenné also I am perfectly satisfied, and agree with Mr. Rivers that it is "the very best very early Pear." Beurré Giffard, though placed among the dozen best Pears in catalogues, and growing well and fruiting well, is to me so very disagreeable in flavour that I have expelled it. Madame Treyve, most healthy, needing root-pruning vigorously, but on the whole a satisfactory Pear. Napoleon, healthy, but not yet fruiting like Beurré Hardy. Louise Bonne of Jersey with all its excellencies I find rather apt to canker, while Josephine de

Malines is perfectly healthy. Among Apples I omitted Hambleton Deux Ans, which with me as an espalier cankers badly.

My plan is, so far as my limited room allows, to increase the number of those Apples which prove with me the very best, such as Lord Suffield, Ecklinville Seedling, and Dumelow's Seedling. No words can overpraise them or Irish Peach. Some others answer fairly, while a few I get rid of if wholly unsatisfactory. This allows me room to try some that I hear or see of reputed excellence ; but I must own as to Pears I am not by any means satisfied, and should be glad to hear of some thoroughly satisfactory as pyramids, praised but not overpraised. With many I find there is vigour and freedom from disease, but in spite of root-pruning no satisfactory crop, while with others disease. I should be glad to have more as "all round good," as Jargonelle, Summer Doyenné, and Bergamotte d'Esperen, and I think my experience is that of many more. Has it come to this, that in our changed climate Pears to prosper must have walls? Bush fruit is satisfactory if there be knowledge and care. Raspberries and Strawberries are also satisfactory, but neither Plums, save the very hardiest, and Pears only a very few do well in the open. Of course I put out of reckoning such very bad summers as that of 1879. There is hope for us next year, as the abundance of sun this summer appears to have ripened the wood well.

As to Apple culture, I should like to see it greatly increased, for it is, if judgment be exercised, a sure crop. Why, then, should we owe so many thousand sacks to America when we might grow all we want at home? One thing people seem to shrink from—viz., grubbing up old useless Apple trees. There are two other Apples I think very highly of—namely, Duchess of Oldenburgh and Annie Elizabeth, neither can I do without the Old Keswick Codlin. One hint let me give to those circumstanced as I am with only a small garden. I never grow any Apple that will not cook. There are plenty which are good at dessert which will also if necessary boil or bake well. A few years ago I disposed of all the "leather coats." I exterminated Braddick's Nonpareil, Pitmaston Nonpareil, and another, being determined that all my Apples should do double duty. This plan I recommend to others unless they have large gardens or are content with fewer varieties than I am, though I rather expect as my fruit experiments continue I shall have to come down to fewer varieties than I anticipated.

I should be unfeignedly glad if any amateur would state what Pears he has found do well, thoroughly well, as pyramids, being satisfactory in growth and fruit in average years.—WILTSHIRE RECTOR.

OXFORD BOTANIC GARDEN.—No. 2.

LAST week I very briefly reviewed the history of this Garden from its establishment until the present time, but there are some portions of that history which deserve fuller notice, especially as regards the most eminent of the gentlemen who held the professorship of botany. For this reason a few additional particulars concerning their lives and works may suitably precede my notes on the plants contained in the garden.

Returning to near our starting point, I have already stated that Dr. Robert Morrison was the first professor appointed, and perhaps there was at that time scarcely another man equally well fitted for the post. He had long been an ardent student of botany, had most creditably superintended the Duke of Orleans' noted garden at Blois, and was subsequently appointed superintendent of the Royal Gardens in England by Charles II. When in 1669 he applied for the professorship at Oxford, for which provision had been made by the Earl of Danby, he had acquired considerable fame by his writings and learning. It is said, probably with some degree of truth, that his "Hortus Blesensis" contributed greatly to the success which attended this application, as it was for that period a really advanced scientific work. Not only was classification attempted on a reasonable basis, but the spontaneous generation theory that was then accepted by many who held high positions in the scientific world was directly and lucidly opposed. Having obtained the appointment, however, he commenced a series of lectures which were exceedingly well attended, but the "Historia Plantarum Oxoniensis" that he subsequently engaged in preparing occupied so much of his time that they were partially discontinued. This great work Morrison did not complete, but after his death in 1683 the younger Bobart finished a portion of it. Passing over a period of about forty-five years, which requires no further mention than was accorded last week, we come to the appointment of Dillenius as professor. This celebrated botanist was a native of Darmstadt in Germany, and first owed his reputation to a work he published on the plants around Giessen, at which university he was educated. Dr. William Sherard when

travelling on the continent made his acquaintance; perceiving that he possessed more than ordinary talent, and an equal interest in cryptogamic plants served to cement their friendship. He persuaded Dillenius to accompany him on his return to England, where he subsequently ensured his appointment as professor by a condition in his bequest to the Oxford Garden. As already stated Dillenius applied himself specially to the study of cryptogams, and his "*Historia Muscorum*" is considered as his most important work. It was illustrated by drawings and etchings executed by himself that imparted to the work a character of great excellence—sufficient, indeed, to justify the observation of Dr. C. Daubeny more than a hundred years later, that "in spite of subsequent improvements, the labour, accuracy, and discrimination displayed throughout the work will prevent it from ever becoming obscure."

There is one other professor of whom a few additional notes may be interesting—namely, Dr. John Sibthorp, who succeeded his father in 1784. He devoted himself most ardently to the advancement of botany and the improvement of the Garden by extending the collections of plants grown there. He travelled much in Greece and the islands of the Archipelago, making a large collection of specimens, of which he subsequently left the majority to the Oxford herbarium. It was during these journeys that he gained much of the knowledge embodied in the "*Flora Græca*," a justly celebrated work. To insure the publication of this he bequeathed an estate, the income from which was to be first applied to that purpose, and finally to the establishment of a professorship of rural economy. Many years elapsed before the first part of his design was completed, and then the costliness of the work—viz., 240 guineas, placed it beyond the reach of the majority of botanists.—L. C.

LUXURIANT VINES.

THE examples of Vines cited by "R. P. B.," page 442, must be unique in their way. I have had a good deal to do with Vines, but never before heard of canes of any degree of strength or length that were so destitute of eyes or buds at their base as to render it necessary to leave more rod than was desirable in order to secure a "leading bud," or which necessitated the leaving of the laterals in order to obtain shoots the following year. When a Vine produces leaves it is bound to produce eyes also, and no matter how weak these may be, they will break if the cane be cut back to them, just as strongly as the strongest, if there be vigour in the Vine. But in "R. P. B.'s" Vines there are, it appears, no Vines at all, which is very strange. There is a sequel, I am afraid, to your correspondent's strange story that has yet to be told. I should think it would interest the Editors to look at them, or a sample of them, for I venture to think they never saw the like before. Has "R. P. B.'s" Vines by any accident or treatment burst their permanent buds and pushed away from home? They would do this if the laterals were pinched below the first joint, but I cannot think your correspondent would do that, otherwise his story is altogether incomprehensible. I rather, however, congratulate him on being prevented from cutting down "luxuriant Vines," as the title of his article conveys, to "within a foot of the ground." The professed object of restrictive pruners in cutting back short is to increase the vigour of the cane, though no one has ever been able to explain the philosophy of the practice; but when "R. P. B." has already canes so vigorous that they have "buried" their base buds in their bark, what does he want to cut them down to the root for?—A PUZZLED GARDENER.

CHRYSANTHEMUM SHOWS.

THE season of Chrysanthemum exhibiting is of brief duration, and in consequence nearly thirty shows have been announced to be held from the 11th to the 25th of November, or in about a fortnight. More than a dozen of these have already been held, but as several occurred on the same day—on Wednesday, for instance, there were six—it was impossible to obtain notes of all. Those reported below are some of the most important, and the varieties enumerated include all that are generally grown for exhibition. It will be found that the Chrysanthemum is by no means decreasing in popularity, for the entries in the chief classes are numerous in most instances, and the quality as a rule shows no falling-off from previous years, although some stands we have seen were obviously spoiled by the immaturity of what would have been fine blooms a little later.

BRIXTON AND STREATHAM.

Last year the first exhibition of the season was held by the Lambeth Society; this year, however, Brixton was to the fore, and well maintained the credit of the Society in a bright and satisfactory display. Critically examined there was noticeable a certain degree of

roughness in a few of the exhibits that was not so marked on some past occasions, yet there were compensatory qualities in others that nearly restored the balance, and by the aid of Mr. W. Hall's tasteful arrangement and excellent management an effect was produced that gave general satisfaction.

Chrysanthemums were as usual strongly represented, fifteen classes being devoted to specimen plants and cut flowers, nearly fifty collections being staged. Following the order of the schedule the first class was for six specimen plants, large-flowered varieties. Mr. W. Hall, Secretary to the Society and gardener to W. Stevens, Esq., Tulse Hill, was deservedly awarded the chief prize for well-grown vigorous plants of the following varieties:—Mrs. Dixon, Julie Lagravere with large well-formed blooms, Mrs. George Rundle, Lady Hardinge, Mrs. Halliburton, and Mr. Brunlees, all fairly well flowered and particularly fresh in the colours. Mr. E. Cherry, gardener to Mrs. Gabriel, Streatham, followed closely with healthy specimens, including a good example of Dr. Sharpe. Mr. J. Howes, gardener to Mrs. Bennett, Upper Tulse Hill, was awarded the remaining prize for strong plants but rather deficient in flowers and too formally trained. The best six dwarf-trained Pompons were staged by Mr. J. Howes, Mdle. Marthe, Sunset and Sœur Malines, being noteworthy for their profusion of flowers, while Mr. G. Cherry took the second place with moderately good specimens. Pyramid Pompons were not in excellent condition; the best were those from Mr. J. Howes, Mr. Hall, and Mr. C. Livermore, gardener to Frederick Webb, Esq., Christchurch Road, who gained the chief prizes. Three noteworthy collections of three standard Pompons were staged, the premier prize being awarded to Mr. J. Howes for Lilac Cedo Nulli, Sunset, and La Vogue, well grown and flowered. Messrs. Livermore and Hall followed closely in the order named. The same exhibitors, with Mr. J. Weston, gardener to D. Martineau, Esq., Clapham Road, and Mr. Cherry, also carried off the prizes in several other classes for specimens that do not require special mention.

The cut flower classes for Chrysanthemums contained several handsome collections, although, as we noted above, some degree of roughness was observable in a few instances. In the open class for twenty-four incurved varieties there was no competition, one collection only being staged by Mr. A. Holmes, gardener to A. B. Hill, Esq., Clapham Park, who was awarded the first prize. The blooms were fresh and clean, and included several unusually fine. The following were well shown:—Mrs. Dixon, White Venus, Aurea Multiflora, Refulgence, Lady Slade, Lady Talfourd, White and Golden Beverleys, and Baron Beust. In the corresponding "district" class there was also only one entry; Mr. J. Holmes, gardener to G. M. Storey, Esq., Nightingale Lane, being accorded the premier award for a similar collection to the last-named, but with rather smaller blooms. Five exhibitors appeared in the class for twelve incurved blooms, Mr. Livermore gaining the coveted position with remarkably neat specimens; George Glenny, Mrs. Dixon, Hero of Stoke Newington, and White Globe were the best. Mr. J. Howes and Mr. W. Clarke, gardener to J. Rains, Esq., Nightingale Lane, were second and third respectively. The prizes for six incurved were well contested, eight collections being contributed. The prizetakers were Mr. John Davy; Mrs. Drew, Streatham; Mr. C. Livermore; Mr. J. Salter, gardener to J. Southgate, Esq., Leigham Court Road; and Mr. A. Holmes, all staging fresh and neat blooms. One class was devoted to Japanese varieties—namely, for twelve, and in this four collections appeared. Mr. J. Holmes was first with handsome blooms, large and good in colour. The best were The Sultan, Nuit d'Hiver, Elaine, Peter the Great, Fair Maid of Guernsey, and Gloire de Toulouse. Mr. W. Horsham, gardener to J. Kempster, Esq., Clapham Rise, and Mr. J. Young followed. In the class for eight large Anemone varieties, twelve blooms, Mr. J. Young was first with an excellent collection, which included King of Anemones, Gluck, Prince of Anemones, Lady Margaret, Louis Bonamy, and Fleur de Marie. Mr. Livermore was second, and Mr. F. Fulbrook, gardener to Mrs. Hyatt, 5, Palace Road, third with smaller but fresh blooms. For twelve Anemone Pompons, three blooms of each, accompanied by foliage, Mr. Livermore was the only exhibitor, and gained the first prize with a collection that has rarely been excelled. The blooms were large, but of admirable symmetry and clear in colour. The varieties were Dick Turpin, Mr. Astie, Marie Stuart, Madame Montels, Perle, and Antonius. The only other class requiring notice was that for twelve incurved varieties from growers who had not taken a prize for Chrysanthemums before. There were two exhibitors. The best collection was staged by Mr. T. Hill, gardener to the Rev. H. Ralph, Clapham Common; but it was disqualified, as it included duplicates. The first prize was consequently obtained by Mr. J. Swain, gardener to Mrs. Wilson, Tulse Hill. A first-class certificate was awarded to Mr. Salter for a white sport from the Japanese James Salter, named Lady Selborne. It exactly resembled the parent in shape, but had not a tinge of colour, the white being quite pure. It was very distinct and attractive.

Among the miscellaneous exhibits which contributed to the display were fine-foliage plants and Ferns; Messrs. H. Wright, Fulbrook, Young, Howes, Clarke, and Davy being the chief exhibitors. Orchids, Primulas, and table decorations were also well shown, among the first-named being a good specimen of *Cypripedium insigne* from Mr. Hall.

Fruit, particularly Pears and Apples, were not only numerous shown but were of remarkable excellence; fine, clean, well-matured

specimens being staged in all the classes. For three dishes of dessert Pears there were ten entries. Mr. W. Collins, gardener to J. Seligman, Esq., Clapham Park, obtained the first prize with admirable fruit of Duchesse d'Angoulême, Passe Colmar, and Marie Louise. Messrs. A. Holmes and Hall were awarded equal seconds, and Mr. H. Wright was third, all with excellent fruit. For three dishes of kitchen Apples there were a similar number of entries, Mr. J. Holmes being first with Blenheim Pippin, Alfriston (very fine), and Emperor Alexander, all of great size and good form. Mr. E. Gates, gardener to S. G. Tulwyche, Esq., and Mr. G. Plumbridge, gardener to Dr. Markham, Nightingale Lane, followed closely with fine fruit. Nine collections of dessert Apples were staged; Mr. J. Foote, gardener to Mrs. Tredwell, Streatham Hill, being awarded the chief prize for excellent examples of Blenheim Pippin, Ribston Pippin, and King of the Pippins. Mr. John Rockill, gardener to Mrs. Falconer, Clapham Park, Messrs. W. Collins and J. Holmes, securing the remaining prizes. Grapes were rather poorly represented.

Vegetables were well exhibited by Messrs. Emmery, Swain, Livermore, Davy, Gates, and Wright, the three first-named in the class for fifteen kinds of vegetables, and the others in the smaller class. All were fresh, clean, and good.

LAMBETH.

That the Chrysanthemum will thrive in some of the smokiest districts of our great cities is well known and has been frequently exemplified, but never, perhaps, has the surprising adaptability of the plant been better shown than by the half dozen exhibitions which the Borough of Lambeth Amateur Society has held since its commencement. Both cut blooms and plants have been produced in creditable condition, although the majority of the exhibiting members reside within a radius of a mile and a quarter of the Elephant and Castle, a district by no means noted for the clearness and salubrity of its atmosphere. The Exhibition opened on Tuesday last well maintained the fame of the Society, although some of the collections suffered severely in the snow and hail storms a few weeks since, and in consequence specimen plants were not quite so numerous as might be desirable. The classes devoted to cut blooms were, however, fairly represented, and the competition in some instances sufficiently close to necessitate careful deliberation on the part of the Judges. The Lecture Hall in the Borough Road was as usual chosen for the Exhibition, the plants being arranged near the walls and forming a bank at one end of the Hall, while the blooms occupied a table in the centre, the general disposition of the exhibits being very satisfactory. In addition to the ordinary prizes for the members residing within the radius named above, honorary members were allowed to compete among themselves in all the classes, similar prizes being awarded to them.

Among the specimen plants the two most noteworthy classes were those for six dwarf and six standard Pompons. In the first named Mr. Ball secured the chief prize, a silver cup, with well-grown healthy plants of the White, Lilac, Bronze, and Golden Cedo Nullis bearing good characteristic flowers. Mr. Clarke was placed second with a collection very near to the first in vigour and careful training, but slightly deficient in the number of blooms, the only point against him. Mr. W. J. Summers, the Honorary Secretary, Falmouth Villa, Sidcup, was awarded the first prize for six standard Pompons bearing an abundance of good blooms, and indicating by their fresh appearance the careful treatment they had received. Calliope, White and Lilac Cedo Nullis were notable, but a specimen of the beautiful Anemone Pompon was superb; not only were the blooms of great size and excellent form, but they were also unusually abundant. Standard large-flowered varieties were admirably shown by Mr. Willsher, who gained the cup for six, including neat examples of Mrs. George Rundle and George Glenney; Messrs. Tracy and Crisp closely following in the order named. Mr. Tracy secured the first prize for a neat group containing several fine plants. Other pyramids and standards were shown by Messrs. Willsher, Fill, and Crisp.

In the cut blooms the Japanese were admirably represented both in numbers and quality. In the honorary members' division of the class for twelve Japanese blooms, not less than eight varieties, Mr. Summers was first with a handsome, bright, and creditable collection. Elaine, The Cossack, Bouquet Fait, Fulgore, Arlequin, James Salter, and Fair Maid of Guernsey being excellent. Mr. Richards took the second place also with brightly coloured specimens, Garnet being especially noteworthy. The district members contributed satisfactory collections, and were placed in the following order:—First, Mr. Crisp, with Elaine, Garnet, and Gloire de Toulouse, very fine; second, Mr. Halstead; and equal thirds, Messrs. Clarke and Ball. With six varieties Messrs. Summers and Clarke were first in each of their respective divisions, Messrs. Halstead, Crisp, and Ball taking the remaining prizes. Incurved varieties were chiefly exhibited by Messrs. Summers, Richards, Ball, Tozer, Halstead, Crisp, and Fill, the collections of the four first-named being similarly placed at the heads of the classes for twelve and six blooms. The majority were fairly good, especially considering that they were shown as grown, and had not been submitted to the manipulation of dressing. For twelve Anemones Mr. Richards was deservedly awarded the first prize, the blooms being uncommonly large and bright; the same exhibitor also staged fine examples of Anemone Pompons, securing the chief prize for twelve trusses. In the corresponding class for six trusses Mr. Ball had a neat premier collection including Antonius, Astrea, Firefly, and Miss Nightingale, very good.

The energetic and enthusiastic Secretary, Mr. Summers, is, as will

be seen from the preceding notes, a more than ordinarily successful grower of the Chrysanthemum, and some of the best exhibited were from his garden. He thus has a double interest in the successful management of the Society's affairs.

STOKE NEWINGTON.

"The best Show we have had," was the frequently expressed opinion on Monday last of some of the oldest Chrysanthemum growers connected with this Society; and certainly the number of fine specimen plants, the profusion of their flowers, with the excellent cut blooms which filled the large hall, seemed amply sufficient to justify the remark, as it was difficult to imagine a more effective display. About 160 handsome plants were staged—so many that the accommodation was scarcely adequate, and in some parts there was an unavoidable approach to crowding. A long table in the centre of the hall contained some hundreds of blooms, chiefly incurved varieties, which were very strongly represented, and at one end was an elevated group of dwarf Chrysanthemums backed up with large Palms and other fine-foliage plants. The whole arrangement was eminently satisfactory, and the Superintendent of that department, Mr. Robert Oubridge, deserves much praise for the taste displayed. It was unfortunate that on the opening day the weather proved most unpropitious, rain falling heavily during the afternoon and evening; yet a large number of visitors were undeterred by that, and in the later part of the evening the building was crowded.

Nine classes were devoted to plants, the chief being that for the best collection of ten specimens tastefully arranged, in which the prizes consisted of a six-guinea silver cup, £2 10s., and £1 10s. There were five entries, the plants entirely occupying one side of the hall. The winner of the cup was Mr. G. Prickett, gardener to Mrs. Bowerbank, Stoke Newington Lane, his group containing standards, pyramids, and dwarfs, well flowered and healthy. A standard specimen of The Cossack was especially noticeable, its brightly coloured blooms being very telling among the other lighter or duller-coloured varieties. The effective Pompon Bob was also well shown, and many others were similarly good. Mr. J. Howes, gardener to Mrs. Bennett, Tulse Hill House, followed with a handsome collection, very near to the first in merit—indeed, some experienced growers considered it superior. Dwarf plants of Sœur Malines, Faust, and Mlle. Marthé were flowering most profusely. The third position was obtained by Mr. D. Donald, gardener to J. G. Barclay, Esq., Knott's Green, the plants fresh and good but rather formally trained. Mr. J. Balaam, Vine Nursery, Clapton, was awarded chief honours for six large-flowered varieties; all were well grown, but Mrs. Forsyth was particularly fine. Mr. Donald secured the second prize with neat examples of good varieties. In the corresponding class for four Mr. J. Balaam was again to the front, followed by Mr. Donald and Mr. F. Wells, gardener to W. A. Smee, Esq., The Limes, Stoke Newington. The best four standard large-flowered varieties were staged by Mr. S. Gilbey, gardener to B. Booth, Esq., Clapton, neatly yet not too formally trained. Mr. Prickett took the second place, and his Violet Unique and Antonius were bright and healthy. Pompons were profusely flowered, the best specimens being those in the class for six. In that Mr. J. Howes was the most successful, the chief plants in his collection being Sunset, Mlle. Marthé, and St. Michael in admirable condition. Mr. M. Butcher, gardener to R. A. Glover, Esq., The Priory, Hadley, Barnet, was a praiseworthy second with specimens bearing surprisingly abundant blooms, and Mr. F. Wells secured the third position. The two last named held relatively similar positions in the gardeners' and amateurs' class for four, followed by Mr. A. Andrew, gardener to J. Wright, Esq., Rosslyn, Stamford Hill.

Cut blooms were, as we have already indicated, remarkably fine and numerous, especially the incurved varieties. The first three classes were devoted to nurserymen and gardeners of Hackney, the exhibits being highly creditable to the district. The best twenty-four varieties were staged by Mr. W. Martin, gardener to J. Appleford, Esq., The Cedars, Stoke Newington, thus winning the silver cup. The blooms were large, symmetrical, even, and compact, the undermentioned being unusually fine—viz., John Salter, Princess of Wales, White Venus, Barbara, Rev. J. Dix, Refulgence, Mrs. Heale, Nil Desperandum, and Princess Beatrice. Mr. Gilbey was placed second, but the blooms were handsome, one specimen of Eve being greatly admired. There were five exhibitors of twelves, Mr. Martin again taking first, showing Lady Hardinge, Refulgence, and Prince Alfred well among others. The second and third collections from Mr. C. Young, gardener to J. Thompson, Esq., and Mr. G. Chalkley, gardener to J. R. Droop, Esq., both of Stamford Hill, were close in quality but fairly placed. In the open class for twenty-four distinct varieties, Mr. W. R. Strong, gardener to Mrs. David Reid, Henwolde Court, Virginia Water, was the most successful, and he was clearly entitled to the distinction accorded him, for the blooms were remarkably fresh, of excellent form, and well selected. Baron Beust, Lady Talfourd, Prince Alfred, Cherub, Empress of India, and Lady Harding were the best among many that were good; Mr. W. Monk, gardener to W. Fowler, Esq., Forest House, Leytonstone, being second with much smaller but neat examples. For twelves in the same section, Mr. J. Hawke, gardener to J. Patterson, Esq., Melrose, Stamford Hill, was first, followed by Messrs. Monk and Wells, all contributing clean fresh blooms. The district amateurs' classes were well filled, Messrs. Coldwell, Broughton, and Wright taking the chief prizes. Mr. W. Butcher easily secured the principal award for twelve Anemone Pompons with a beautiful collection, including Marie

Stuart, Mr. Astie, Regulus, Perle, Mr. Wyness, and Antonius in admirable form. Three stands of Japanese varieties were exhibited in the class for twelve blooms, and Mr. R. Strong was accorded first honours for specimens of great size, and some very brilliant in colour. Yellow and Red Dragons were fine, especially the former, Fulton and Cry Kang, bright; and Elaine, very large. Mr. W. Monk followed with smaller but even blooms, Mr. Donald securing the third position. A first-class certificate was awarded to Mr. Peachey, Stamford Hill, for an incurved Chrysanthemum named *Angelina*, said to be a sport from Lady Slade, which it resembled in form, but the colour was more in the way of Barbara, though lighter.

A few fine-foliage plants with some miscellaneous exhibits were also contributed, but they do not demand special mention, though the handsome collection of Chrysanthemum blooms from Mr. Cochrane, Finsbury Park, deserve noting. Taking the Exhibition generally it was very satisfactory, and Mr. Goldsmith may be complimented upon the success that has attended his efforts.

PUTNEY AND DISTRICT.

The third Exhibition of this Society was held in the Assembly Rooms, Putney, on Tuesday last, and was by far the finest display that has been seen there; indeed the groups of Chrysanthemums have probably never been surpassed at any show. The large room was crowded with plants almost from the floor to the ceiling, and the cut blooms on the central tables with fruit and plants for table decoration, combined to render the effect highly imposing. It is quite clear that this district includes excellent cultivators, and their endeavours to improve themselves in their calling and afford a rich floral treat to the inhabitants of the district will, we trust, meet with the support they deserve from the affluent section of the local community.

The limited time and space at our disposal compel us to refer to the Show in the briefest possible terms. In the chief class a collection of Chrysanthemums in not less than twenty varieties, to occupy not more than 40 superficial feet of space, the first prize, a silver cup, was won by Mr. Harding, gardener to T. D. Galpin, Esq., Bristol House, Putney Heath, with a splendid group, the plants being on single stems, each having from four to eight blooms of the first exhibition size and quality, and the foliage was as good as the blooms. John Salter was remarkably fine, and a reflexed pink variety resembling Wells' Queen commanded attention by its extraordinary flowers. Mr. Ward, gardener to H. Hoskier, Esq., Solna, Putney, was an extremely close second; Golden Empress of India, Barbara, and Faust in this group were not surpassed if equalled by any plants in the Show. Mr. Handley, gardener to Miss Pearson, Victoria Road, was placed third with a most meritorious group, and Messrs. Mahood and Son, Windsor Nursery, Putney, fourth with a collection little inferior. Mr. Stevens, St. John's Nursery, Putney, and Mr. Bennett, gardener to F. Rodwell, Esq., Feldheim, Park Road, Wimbledon, were worthily awarded extra prizes for collections of undeniable merit.

Mr. Bentley, gardener to Sir T. Gabriel, Bart., Edgumbe Hall, Wimbledon, well won the foremost position in the class for six plants in 1½-inch pots with healthy informally trained specimens; Mr. Pithers, gardener to F. C. Williams, Esq., Munster House, Fulham, being second. For three plants the chief prize was won by Mr. Hoskins, gardener to W. V. Williams, Esq.; and for a single specimen honours fell to Messrs. Bentley, Mahood & Sons, and Hoskins in the order named. The last-named exhibitor received the chief prize for six Pompons, followed by Mr. Ansell, gardener to G. Reid, Esq., Coombe Villa, and Mr. Pithers. For three plants Messrs. Bentley, Hoskins, and Pithers were the prizetakers; and for specimen plants Mr. Hoskins and Messrs. Mahood & Son. As a rule the plants were much too closely tied, and more freedom is highly desirable.

Of cut blooms the display was not extensive, but the winning stands contained many excellent flowers. Mr. Berry, gardener to the Countess of Leven and Melville, Roehampton House, was the premier exhibitor, being first for twenty-four blooms, twelve blooms, and six blooms, incurved varieties; second for twelve and first for six Japanese blooms. Mr. Holmes, gardener to G. M. Storey, Esq., Nightingale Lodge, Balham, was second for twelve incurved blooms, the remaining prizes in these classes falling to Messrs. West, Bentley, and Holmes. Messrs. Mahood & Son had the chief prize for Japanese varieties with very large and fine blooms; but Mr. Berry's stand contained brighter flowers.

Several collections of Ferns were staged which call for no comment, the prizes going to Mr. Stevens; Mr. Martin, gardener to J. Brandreth, Esq., Devon Lane, Wimbledon; and Mr. Handley. Primulas were largely represented, the first-prize plants of Mr. Woodhams, gardener to R. Davis, Esq., St. Ann's Hill, Wandsworth, being very dwarf and good; the second (Mr. Ward), also good; and the third (Mr. Mahood's), very fresh. Zonal Pelargoniums from Mr. Bennett and Mr. Bartley—the prizetakers—were well flowered, and plants for table decoration were clean, bright, and good, the successful competitors being Messrs. Bennett, Pithers, and Bentley.

Fruit was good. The first prize for black Grapes was won by Mr. Martin with Black Hamburg in excellent condition; the second by Mr. Ward with admirably finished Lady Downe's; and third by Mr. Bennett with Black Alicante. Mr. Ward staged in the class for white Grapes Muscat of Alexandria of superior quality, and easily secured the foremost place, Mr. Bentley being second with the same variety, and Mr. Martin third with Early Ascot Frontignan of excellent flavour. Culinary Apples were very fine, and dessert Apples good; Pears only of moderate quality. The principal prizetakers in

those classes were Messrs. Haines, Ward, Fanning, and Pragnell, gardener to F. J. Baring, Esq., M.P., The Cedars, Roehampton.

Prizes were given by Mr. Stevens for groups of plants arranged for effect, Mr. Pithers easily securing the first position; by Mr. Mahood for bouquets of Chrysanthemums, and Mr. Moore for hand bouquets, Mr. Pragnell being the winner in both classes. Many of the bouquets were much crowded, and were consequently passed by the Judges. Prizes were also offered for stove and greenhouse plants, and won by Mr. Stevens and Mr. Pithers.

A luncheon was held after the completion of the judging, G. H. Pitt, Esq., a valued supporter of the Society, presiding, supported by Mr. Moore the courteous Secretary.

WALTON AND HERSHAM.

As usual a remarkably beautiful and attractive display greeted the numerous visitors to the Walton Show on Tuesday last, both plants and blooms being excellent; indeed, some of the collections of the latter have rarely been surpassed. Mr. G. Masters, the courteous and enthusiastic Secretary, deserves much credit for the satisfactory arrangements, and we regret that the limited time at our disposal only permitted us to give a comparatively brief report.

Plants.—The collections of six dwarf incurved varieties were very effective and good. A very fine bank at one end of the building was formed of the plants in this class, the specimens being healthy and remarkably well flowered. The first prize, consisting of a watch value four guineas, was awarded to Mr. Lavey, gardener to Mrs. Wilson, Walton, the varieties represented being Alfred Salter, Mrs. Forsyth, Mrs. Dixon, George Glenny, Dr. Sharpe, and Christine, even and handsome. The second position was accorded to Mr. Burns, gardener to H. A. Riggs, Esq., Hersham, who followed very closely with similarly well trained and profusely flowered specimens, some of the varieties being a little past their best, but otherwise indicating very careful culture. Mrs. G. Rundle and Mrs. Dixon were particularly fine. Mr. Reynolds, gardener to Mrs. Allen, Weybridge, was third with a fair collection. The collections of four formed a bank at the opposite end of the room, and, though not quite so compact as those in the first class, the flowers were of good size and very abundant. Mr. Cornhill, gardener to E. Pettit, Esq., Oatlands, secured the chief award with neat examples of Mrs. G. Rundle and Venns among others. The second prize went to Mr. Millican, gardener to Mrs. Cobbett, Walton, with specimens but little inferior to the first. Mr. Polley, gardener to H. Rogers, Esq., Oatlands, took the third prize with bright specimens.

Standards were fairly well shown, but not in great numbers. For four large-flowering varieties Mr. Millican was accorded the chief honours with admirably grown and well trained specimens, Mrs. G. Rundle and Mrs. Dixon being especially noteworthy; Mr. Polley was a good second, but the specimens were rather loosely trained. Mr. Cornhill obtained the third place with moderately good plants. Mr. Burns had the best pair of standards, and Mr. Lavey followed closely, both staging fine examples of Mrs. G. Rundle and Mrs. Dixon. Mr. Lavey staged the best single Pompon, and large-flowered specimens, healthy, vigorous, and bright.

Pompons were very numerous and extremely good. For six dwarf plants Mr. Reynolds was first with even and handsome specimens, Calliope, Antonius, Louisa, and Mdle. Marthe being the most noteworthy. Mr. Cornhill was a close second, Bob, Mr. Astie, and Antonius bearing a profusion of blooms. Mr. Millican was a fair third, his Dick Turpin was particularly bright; Messrs. Lavey and Polley sharing equally well in the class for pairs. Mr. Polley had four handsome standards and easily secured the premier prize, the varieties Antonius, Marie Stuart, Madame Montels, and Marguerite de Coix being finely represented; Messrs. Cornhill and Millican followed, but far behind. Messrs. Lavey and Reynolds were the prizetakers for pairs.

Cut Blooms.—There were five entries in the open class for twenty-four incurved blooms. Mr. Strong, gardener to Mrs. D. Reid, Virginia Water, staged the premier collection of twenty-four in the open class, the blooms being large and of excellent form; especially noteworthy were Guernsey Nugget, Venus, Lady Harding, Baron Beust, Princess of Wales, Barbara, Nil Desperandum, and Empress of India. This very handsome collection well merited its position. The second prize was awarded to Mr. Burns for a fine collection, including an extraordinary Empress of India, with Lady Talfourd, Faust, and Venus among many others extremely fine. Mr. Hill, gardener to A. Savory, Esq., Chertsey, was placed third with smaller but even blooms. Mr. J. Strong, gardener to H. Sweet, Esq., Weybridge, was first with twelve, Lady Harding and Nil Desperandum being the most remarkable. Messrs. Millican and Lavey secured the remaining prizes in that class with creditable specimens. In the Society's district class for twenty-four incurved varieties Mr. Reynolds was an excellent first with blooms of good substance, Messrs. Burns and Cornhill taking the second and third prizes in that order. With twelve Messrs. Burns, Polley, and Reynolds were the successful exhibitors, all staging very good specimens. Mr. Cornhill was placed first with a beautiful collection of twelve reflexed varieties, including fine specimens of Progne, Chevalier Domage, Dr. Sharp, Ariadne, and Wells' Queen. Messrs. Reynolds and Polley took the remaining prizes.

Japanese varieties were well shown, the blooms being unusually large and bright. Mr. J. Strong had the premier collection of twelve, comprising handsome blooms of Gloire de Toulouse, Triomphe du

Nord, Bouquet Fait, Sultan, and Mr. Delaux; Mr. Millican was a very close second, and Mr. Polley third. A handsome collection of twenty-four was exhibited by Mr. Burns, who deservedly secured the chief award. The blooms were large and particularly bright in colour. Garnet, La Nympe, The Daimio, Yellow Dragon, and Nuit d'Hiver were extraordinary. Mr. Reynolds was second also with fine specimens, Mr. Cornhill taking the third prize with smaller but neat blooms. Mr. Reynolds was awarded first for a handsome collection comprising Lady Margaret, King of Anemones, George Sands, Gluck, and Sunflower, all fine. Messrs. Cornhill and Millican followed in the order named with smaller but fresh even blooms. In Anemone Pompons Messrs. Cornhill, Polley, and Millican contributed beautiful blooms; Messrs. Lavey and Reynolds being similarly strong in the ordinary Pompons. The competition for the table decorations and bouquets was close, and considerable taste was displayed by the exhibitors; Messrs. Reynolds, Strong, Lavey, and Cornhill securing the chief prizes.

PLYMOUTH.

A handsome collection of Chrysanthemums, plants, fruit, and flowers under the auspices of the Western Chrysanthemum Society, were displayed in the New Guildhall, Plymouth, on the 10th and 11th inst., the first that the Society has yet held. Mr. James Garraway, Bristol, competed in several classes for cut blooms, and in each case was awarded first prize. His incurved varieties, Prince Alfred, Lord Derby, Mrs. Dixon, and Aurea Multiflora, were especially fine; and Fair Maid of Guernsey, Gloire de Toulouse, and Nuit d'Hiver amongst the Japanese. Mr. G. H. E. Randle, the pioneer of Chrysanthemum growing in the west, indeed we may almost say in England, also came well to the front, exhibiting largely both in the plant and cut bloom classes, and won several prizes. For the best group of Chrysanthemums, Mr. Brighton, gardener to the Earl of Mount Edgcumbe, was deservedly awarded the first prize with a collection that was well finished both with regard to foliage and flowers. Mr. G. H. E. Randle was placed second, and the Rev. T. A. Bewes third. There were five competitors in this class. Mr. W. Radmore, Admiral Lowe, Messrs. T. Mills, Moist, Hamilton, Whiteford, W. Symons, H. D. Guy, and S. Elliott were all successful exhibitors in the cut bloom classes.

Ferns, Primulas, berried plants, Zonal Geraniums, ornamental shrubs were largely represented, and added greatly to the effect that can be made in such a spacious building as this Society is fortunate in obtaining. Fruit and Potatoes were also exhibited well and numerous. The attendance was more than before another instance of the rising popularity of this fine autumnal flower.

The arrangements of the Exhibition were most ably conducted by Mr. Cooper, the Honorary Secretary, and Messrs. Walling, Pepperell, and Merry of the Executive.

COCOA-NUT FIBRE REFUSE.

PERMIT me to thank your correspondent, "A NURSERYMAN" (pages 365, 366), for his able remarks on the value and uses of cocoa-nut fibre. I can fully endorse all he has said on its good qualities. I wish, however, that he had said a little more on its merits for propagating purposes. My remarks are not intended for old practitioners, as doubtless they have ascertained the value of the material, but I am now writing for amateurs. Cocoa-nut fibre refuse for propagating is unrivalled. I know of no substance to equal it for that purpose, and as "A NURSERYMAN" stated in his remarks that it was cheap, I should strongly recommend amateurs to give it a trial. Silver sand is employed extensively for propagating purposes, and it will be admitted by all that many plants, such as New Holland plants, Ericas, Epacrises, &c., cannot be propagated successfully without it; but we will exclude that section of plants, and leave the nurserymen to propagate them for us. Silver sand is also rather expensive in some parts, and I have seen it used with as great care and economy as if it had been so much gold dust. The fibre is admirably adapted for the propagation of bedding plants in spring, and anyone possessing a small propagating house or pit with bottom heat could not do better than give it a trial. Insert the cuttings into the fibre, and they will be rooted and ready to be potted in a few days.

I have an old bed of fibre that is used for plunging sickly store plants in to recruit their health, starting Achimenes in the spring, &c., and it is surprising how soon cuttings take root by merely inserting them in the fibre. I have seen cuttings of plants that were considered difficult to propagate in an ordinary way, strike freely without any further trouble than making and inserting them in the bed. Such plants as Stephanotis, Hoyas, Dracenas, Allamandas, and Clerodendrons readily strike in this way. It was by this means that one of the most clever propagators around London discovered the method of propagating Aralia Veitchii and A. Veitchii gracillima. It was thought that these fine decorative plants would not strike roots from cuttings, hence the mode of grafting them on A. Guilfoyii was resorted to; but now they are propagated from cuttings by inserting them in fibre in bottom heat. Nothing could possibly be better than a

bed of cocoa-nut fibre for striking flowering and fine-foliage Begonias. For the latter take suitable leaves; cut through the most prominent ribs, and peg them down on to the fibre. In a short time there will be a batch of young plants formed from each leaf, which when sufficiently large can be potted, with a good admixture of the fibre in the soil. It is also invaluable for propagating winter-flowering plants in spring, such as Goldfussias, Eranthemums, Scutellarias, Linums, and a host of others too numerous to mention here. Its uses are manifold, and it only requires to be tested to prove its capabilities.—W. K.

RASPBERRIES.

A NOTE of my thirty years' experience in the cultivation of this fruit, which I believe pays more for the ground which it occupies than any other fruiting plant, may possibly be useful to some readers. About thirty years ago I was convinced that the general plan of tying the canes in a bunch was a mistake, so I experimentalised and put up some posts and wires, to which I tied the canes, but I found that the action of the wind cut them and they broke off in contact with the wire. I then had some hazel rods and also ribs of wood, to which I tied the young canes and had good crops. But to what I now desire to draw the attention of your readers is, Do not allow anyone to cut anything off the shoots of your Raspberry canes—not an inch. When the Raspberries throw up the young shoots have all of them pulled up except four or five at each stool. Allow those to grow, and you may have them as mine are 8 feet to 10 feet long and five-eighths of an inch thick; then train by tying them to the fence in the form of a bow, the highest part of the arched cane being a little above the top of the fence, the end of the cane pointing to the ground. The canes then will produce shoots and fruit from every eye, and keep bearing fruit until the frost cuts them down.

The Raspberry grows best in a moist, rich, deep soil, where its roots are not exposed to the action of the sun, and is greatly benefited by copious supplies of liquid manure during the fruiting season. My rows are 4 feet apart, and the shoots touching each other.—G. O. S.

NEW AND CHOICE PLANTS.—No. 3.

CONTINUING my notes from page 46 upon plants that are remarkable for their novelty, beauty, scarcity, or peculiarity of structure, I wish to draw attention to the following, all of which possess more than ordinary merit, entitling them to the consideration of plant-growers, particularly for large collections, though at least one of them may rank among the plants of general decorative value—namely, the Fairy Rose.

CROTON STEWARTI (Williams).—Crotons, like Dracenas and Coleuses, are now represented by so many forms that the number of really distinct and handsome novelties brought out every year are comparatively few, and they must possess some valuable and clearly marked characters to ensure even a moderate degree of public favour. Croton Stewarti appears to me to be one of those meritorious few, and is likely to gain a high place in the estimation of all who admire richly coloured foliage plants. The finest and most characteristic specimen I have yet seen was shown by Mr. B. S. Williams at the October meeting of the Royal Horticultural Society, when it was greatly admired for the bright clear orange and yellow-coloured bands and margin in contrast with the deep green central portions of the foliage, and relieved by the deep crimson petioles and midribs. The leaves are broad, inversely egg or lance-shaped, and the plant is dwarf in habit, the latter being an important recommendation. Another point, too, is the early stage in which young plants commence showing colour, as that eminently suits them for decorative purposes. It was obtained by Mr. Williams from New Guinea, but whether it be entitled to rank as a species or merely as a variety I am unable to determine, though the latter is the more probable view.

ROSE LITTLE WHITE PET (Henderson).—This charming little Rose has been several times approvingly noted in the Journal, so that it cannot be strange, in name at least, to the majority of your readers. However, my admiration of the plant will perhaps afford some excuse for this reference to it. One of the chief difficulties that amateurs and others whose means of accommodation is limited have to contend with, is the selection of ornamental, easily grown, and generally useful plants out of the multitudes offered for sale, and among which there must necessarily be many totally unfitted to their requirements. It is for this reason that the specially useful plants cannot well be too frequently brought under the notice of the public. Among them the Fairy Rose sent out by Messrs. Henderson & Son is in my opinion worthy of being placed, for its delicate elegance is most pleasing. The common red Fairy Rose is too well known and appreciated to need descrip-

tion here, and in the one named above we have a companion for it exactly similar in habit, but with abundant and neatly-formed white flowers. For greenhouse or conservatory decoration in April and May it is invaluable, especially when grown in 48-size pots. A first-class certificate was awarded for it at the Royal Botanic Society's Show on the 9th of May in the present year.

ERYTHRINA PARCELLI (Bull).—Coral Trees are usually grown for their brilliantly coloured flowers; but the species under notice, though also bearing showy flowers, is chiefly remarkable for its finely variegated foliage. It is not strictly a novelty, for it was sent out by Mr. Bull in 1874, but it is not at present so well known as it deserves to be. As a stove plant it is surpassed by few in distinctness and effectiveness, and being of vigorous growth it is well suited for arranging in the centre of a group or bed. For some time past a good specimen has been notable in the stove at Kew, very satisfactorily indicating the decorative value of the plant. The variegation consists in the midrib and lateral veins of the rhomb-shaped leaflets being of a bright yellow colour, the remaining portion being a deep green tint. The three leaflets that form each leaf are rather distantly placed, and are bent downwards slightly, imparting somewhat of a pendulous appearance to them. Plenty of heat, a light position, and a good compost of loam, leaf soil, and sand, with abundance of water during growth, are the principal cultural requirements of the plant.

ANTHURIUM WAROCQUEANUM (Veitch).—As regards beauty of foliage this species of Anthurium is equal to any in cultivation, indeed when in good condition I consider that it excels the majority. The leafstalks rise to the height of about 2 feet; they are curved at the apex, the blade of the leaf being frequently a yard in length, and turned point downwards, so that they are vertical, with the deeply heart-shaped base uppermost, and the blade tapering gradually down to the point. The colour is a peculiar but beautiful deep green, the surface possessing a fine velvety gloss; that, together with the lighter-coloured distinctly-marked veins, constitutes the chief attractions of the plant. Like others of the genus its home is in tropical South America, Messrs. Veitch having obtained it from New Granada a few years since. Both the Royal Horticultural Society and the Royal Botanic Society have signified their appreciation of its merits by the award of first-class certificates. Though not very difficult to grow there are a few little points in its culture that need special attention, and therefore the following hints may be of service to those who have just obtained or are about to purchase a plant and are in doubt as to the best mode of treatment, especially in potting. In the first place, it must be remembered that all Anthuriums are superficial rooters, so that a great depth of soil is not only unnecessary but positively injurious. Wide and deep pans are the best for these rather delicate species, and quite one-third of their depth should be occupied by the drainage, consisting of carefully arranged potsherds, as it is very important that there be no stagnation. A little moss may be placed over this, and then some of the compost—good fibrous peat, charcoal, sand, and sphagnum well mixed; carefully place the plant in the pan, filling up with the compost several inches above the rim of the pan and surfacing with fresh moss. A few light sticks may be needed to render the leaves and stem firm. A moist stove or a house devoted to tropical aquatic plants suits it admirably, abundance of water being required at the roots during growth, but syringing the foliage must be avoided if possible. A shady position is also needed, as the leaves are quickly injured by exposure to the sun.—R. L.

ROOT PRUNING.

UNDER the above heading I desire to offer a few remarks. Those having fruit trees making vigorous growth and perfecting few or no fruit buds, will possibly have selected them to undergo a course of root-pruning, with a view to improving them. I am of opinion that this is often carried to the extreme, and instead of trees of moderate growth and full of fruit buds, we possess plants full of fruiting spurs and of insufficient vigour to carry a crop to perfection, through the undue use of the knife among the roots.

To obviate this, a trench should be taken out as near as possible at the extremity of the roots (a glance at the branches will probably be the best guide to determine this). Fork-out the soil, and carefully preserve all roots from 3 to 7 feet from the stem of the tree. Let them be placed so that they will not be injured, sprinkled with water, and covered with a mat until they can again be laid in the soil. If the drainage is defective, let it be attended to, as this is the main point in the cultivation of tree or plant. The soil it is desirable to use for this purpose is not always procurable, so that which is at hand must be made to suit the

tree as nearly as possible. If it can be obtained, a good sound fibrous loam, brick and lime rubbish, and a few crushed bones will be found a suitable compost for most fruit trees. Cherries delight in a stronger soil, but they will succeed in the above. If the soil is light a small quantity of brick and lime rubbish will be sufficient. The soil should be made quite firm and rammed well up to the old ball. The roots should be laid level and in the position they occupied before as nearly as possible. Cut only the tips off the roots; and if any portion of the root has been injured in lifting pare it off with a sharp knife, it will most likely emit roots from this point.

By the above method I maintain that a fruit tree, however vigorous, receives a sufficient check to induce fruitfulness, and leaves enough strength in the root to allow the branches to make a moderate growth the following season, and so do away with the practice of cutting off half the roots to throw the tree into a state of fruitfulness and cause permanent injury.

In another issue I will write on training fruit trees.—ROBERT D. LONG.

AMORPHOPHALLUS RIVIERI.

I HAVE had sent to me from Belgium some enormous tubers, as large as good-sized Turnips, but not at all like them, under the above name. I am told they only produce a leaf, no stem, as plants generally do, and that the plants are both curious and

Fig. 83.—*Amorphophallus Rivieri*.

ornamental. Can you give me any information about this plant? What shall I do with the tubers, and where and how should I grow the plants? I shall be pleased to have instructions on the subject from any of your readers.—A STATION MASTER.

[As you live in the south of England you will be able to grow this singular plant, of which we are able to give an engraving, in your garden during the summer; but in the autumn it should be taken under cover, and when the large and peculiar leaves have died store the tubers in sand, or if in pots place them in a dry position. Ordinary light garden soil suits it very well. The stem-like leafstalk is a very dark green in colour, curiously spotted and mottled with lighter tints. It flowers like the Arums, but the spathe is best removed as soon as noticed, for the odour is excessively fetid.]

NOTES ON BIRDS.

SHAKESPEARE was right, as he always is about birds and flowers, when he wrote, "The Blackbird had an orange tawny bill;" still the modern poet was equally right in writing of its having a black one. The one wrote of the old male bird, the other of the female or a young cock of the year. But whilst writing on the subject I may mention that the bill colour of the male varies very much, and in some localities it is such a deep orange it is almost red, while in others it is of a deep golden yellow; also there is much difference in the black colour of the bird

those having the rich red orange bill being of a much more purple black, to the light-billed birds' blue black. Again, the tawny orange-billed birds are mostly neater and smaller than the others. This is not a matter of age, but of bird variation, of which I have taken notice for many years—not only of those in wild state, but also those sent for exhibition to the various shows at which I have had the honour of acting as judge.

Mr. Hiam's notes on the departure of the swallow are interesting, and it would be well if more of the readers of the Journal would from time to time give notes on natural history. I for one would not only read them with pleasure, but be thankful. Mr. Hiam says the swallows finally left his locality (Ashwood Bank, Worcestershire) on the 15th of October. The "SURREY PHYSICIAN" gave the 21st of October for his locality, whilst in mine (Brenchley, Kent) I saw two swallows flying about my grounds on the 7th of November; and walking to Paddock Wood station, about a mile and a half from my house, on the 8th of November I saw three more flying close by the station, and evidently only feeding—not on passage, as they were skimming about the chimneys of the houses. This is later than I ever knew them before, the 1st of November being the latest on my record. I was the more surprised at their not having left, as we have had 8° of frost here registered; still they stayed. I have not seen any since the 8th.

As Mr. Hiam says truly, the bullfinches are numerous this year, and are at work on the Larch buds. How are they best trapped? Will anyone kindly tell me? for I shudder when I think of my Plum tree bloom buds, and hear and see so many bullfinches about. Redwings and fieldfares appeared here at the end of September, and cleared off the Damsons with much zest, and then went on rejoicing. What beautiful birds they are!

As regards Holly berries, a few of my trees have some, others not any, while one is nearly all berries, with scarcely a leaf—a gorgeous sight. I never saw its equal. Heps are most plentiful, and many other berries. The Yews (Irish) are very beautiful and bright with their fruit. The thrushes and robins coming day by day, however, have lessened the crop considerably; also a great tit has been feasting. I never knew they were fond of such diet before, so one lives and learns. Before closing this I may mention that I have noticed it stated that wasps have been very abundant this year in most localities. Here we have had very few, scarcely any trouble at all. Is it possible that the great, blue, cob, and other tits, of which there are many here, have kept them under by eating them? for they have my bees, as they have eaten them all.—HARRISON WEIR, *Weirleigh, Brenchley, Kent.*

AT a General Meeting of the ROYAL HORTICULTURAL SOCIETY held on Tuesday last, Colonel R. Trevor Clarke in the chair, the following candidates were elected Fellows of the Society—viz., Thomas Clifford, George Henry Ellis, R. P. Humphery, Thomas Joseph Saltmarsh, Archibald Seth-Smith, A. W. Travers, James Wallace, and James P. Watts.

— It is somewhat the fashion in these days of agricultural depression to urge upon farmers the IMPORTANCE OF GROWING VEGETABLES FOR MARKET; but we are credibly informed that the season of 1880 is proving far from a prosperous one for market gardeners. It seems that there have been too many vegetables grown to be profitable, and it is questionable if those even who are near to London, and can therefore cart their produce to the markets and load back with cheaply bought manure, have more than covered their expenses. Those at a greater distance who have to send by rail have been especially unfortunate, as frequently the "returns" were nil, or not even sufficient to pay the cost of carriage. Peas were late, and although some crops realised good prices the greater part were ready for picking simultaneously, the consequence being a glut in the markets. The case was still worse with the Runner Beans, a more expensive crop to grow, not being off in time to be followed by a crop of Turnips or other quick-growing vegetables. Good prices were obtained for a few of the

earliest pickings; but later on they were extremely plentiful, and owing to the low prices large quantities were never picked. They were cut down by frosts much earlier than usual. Potatoes, in spite of the heavy crops, especially of the later varieties, have not been very profitable, as prices are low. Many growers would be glad to obtain £5 per ton even for Victoria Regents. Savoys are another crop on which much money will be lost this season, as it does not pay to grow them for digging or turning-in for manurial purposes, yet this is what is being done by those at a distance from London.

— It is common around London to see in gardens of all sizes a good display of CHRYSANTHEMUMS AGAINST WALLS, and it is surprising how well the plants succeed in such positions, the growth being particularly vigorous, and the slight protection afforded by the wall renders the flowers cleaner and more lasting. Our Clonmel correspondent, "W. J. M.," appears to have adopted a similar practice in Ireland, and with considerable success, judging by the handsome flower of the white Fleur de Marie he has sent us, grown against a south-west wall. When a careful selection of varieties is made, choosing those with bright or distinct shades of colour, the effect produced is very satisfactory.

— WE regret to have to announce the death of REV. T. C. BRÉHAUT, chaplain of the Guernsey prison, which occurred on the 4th inst. at his residence, Richmond House, Guernsey. For many years Mr. Bréhaut was a regular contributor to the pages of this Journal on the subject of fruits, and especially on the orchard house and cordon cultivation of fruit trees. He did much to extend and popularise these modes of management, and his views on the subject were fully set out in these pages. Mr. Bréhaut was the author of "The Modern Peach Pruner," published at this office, and also of "Cordon Training of Fruit Trees."

— WE have already many useful variegated plants for decorative purposes; but the CYPERUS LAXUS VARIEGATUS, shown by the General Horticultural Company at the meeting of the Royal Horticultural Society on October the 12th, is entitled to rank among the best. The Committee indicated their appreciation of its merits by awarding a first-class certificate for it, an honour which was well deserved. The plant is dwarf in habit, scarcely exceeding 15 inches in height, and the white streaks in the foliage are very clear and distinctly marked.

— OUR correspondent "C. P. P.," writing to us on the CLIMATE OF VENTNOR, states that "Many fine zonal Pelargoniums are still in bloom, and even fancy Pelargoniums, the dwarf bedding kinds not being injured by frost. The Veronica Andersoni is in very good bloom in the gardens here, where it seems to flourish like the Euonymus. There is also a small plant of Eucalyptus globulus at the back of this house, which is growing freely; but I do not think it was unprotected last winter, but shall make inquiries. There is an old large plant of scarlet zonal Geranium against the house under a verandah, which has lived out several winters."

— MR. SALTER, gardener to J. Southgate, Esq., Selborne, Leigham Court Road, Streatham, exhibited at the Brixton Chrysanthemum Show on Thursday last a very distinct and pretty JAPANESE CHRYSANTHEMUM named LADY SELBORNE, a sport from the well-known James Salter. It has the peculiar form of flower that marks the latter variety, the florets broad and twisted, but pure white. If Mr. Salter succeeds in fixing the sport it will undoubtedly prove a great acquisition. The Judges unanimously accorded it a first-class certificate.

— "R. S." sends us the following note in reference to a LARGE VINERY that is being erected in Jersey:—"It may interest some of your readers to know that Mr. G. Bashford, the well-known Grape-grower, is now having a vinery erected of unusual

size. The particulars of the dimensions have already appeared in the *Builder*, from which I have extracted them. Length 1,100 feet, width 30 feet, superficial area of glass 42,000 feet. Length of 4-inch piping to be employed 10,000 feet. The glazing is to be done on a patent non-puttying system. The house is intended for Vines to yield an early supply."

— THE Annual General Meeting of NATIONAL AURICULA, CARNATION, AND PICOTEE SOCIETIES (Southern Section), will be held at the house of E. S. Dodwell, Esq., 11, Chatham Terrace, Larkhall Rise, Clapham, S.W., on November 23rd, at 3 P.M. Wandsworth Road is the nearest railway station.

— MESSRS. JAMES CARTER & Co., 237, High Holborn, London, have sent us some remarkably fine MAGNUM BONUM POTATOES, with a request that we test their quality when cooked. We have done so and found them excellent. They were white, sufficiently mealy, melting, and of an agreeable and delicate flavour. The Magnum Bonum appears to be one of the few Potatoes that combines size with good appearance, suitable for the exhibition table, great cropping and disease-resisting properties, and the quality, judged at least by all the samples we have tasted, fit for any table. The cooking properties are probably not developed equally early in all cases, as soils exert a great influence in this respect; and we have proved by careful experiment that the large imposing tubers that would secure a first prize at a Potato exhibition are by no means equal in quality to the smaller or medium-sized samples that might by chance obtain a third prize, but, as is more probable, would be passed by the Judges.

— MR. H. CANNELL, Swanley, Kent, recently sent us some spikes of the beautiful SALVIA PITCHERI. Blue flowers are generally rather scarce, but in the middle of November they are especially welcome. The shade, too, possessed by this fine Salvia is one of the clearest and most pleasing represented in flowers. The spikes are 7 or 8 inches in length, cylindrical, very compact, and contain a large number of medium-size flowers. For growing in pots and employing in conservatory and greenhouse decoration this plant will be invaluable, constituting an important addition to our best of late autumn-flowering plants.

— THOSE charming little Orchids, the INDIAN CROCUSES or PLEIONES, are general favourites, owing to their brightly-coloured and pretty flowers being produced at a season when the Orchid house is comparatively dull. During the past month we have seen several handsome displays of *P. lagenaria* and *P. maculata*, Messrs. Veitch and Williams having good collections remarkably well grown. Another pretty species has also been notable at Kew in company with the others—namely, *P. Wallichiana*, similar in habit and flowers to the better known forms.

— ONE of the most elegant of the delicate Filmy Ferns is HYMENOPHYLLUM CILIATUM, which has diminutive pellucid pale green fronds, slightly fringed with fine hairs, as the name implies. This species is not very difficult to manage, as it succeeds well on a portion of Tree Fern stem in a Wardian case. As with others of the genus, the chief requirements are abundant moisture in the air and around its delicate roots, but no approach to stagnation, and a very equable temperature.

— MR. HARRISON WEIR writes:—"The WEATHER IN KENT is all against gardening—frost, snow, rain, mud, slush, mixed, and plenty of it!"

— THE fact that the Rev. Canon Hole's "BOOK ABOUT ROSES" (Blackwood & Sons) has reached a seventh edition is sufficient evidence of its popularity. Written in a style that is at once racy and readable, and containing instruction that is sound and reliable, it meets the tastes of a wide circle of readers. It only

remains to add that the present volume is larger and more varied than the last, is admirably printed on superior paper, and forms an attractive and useful volume.

— MR. J. MUIR of Margam sends us the two following notes—"In the autumn of 1877 HOLLY BERRIES were most abundant on the trees here; in 1878 they were very scarce. In 1879 they were again plentiful, and this year we have not a single berry. Is this scarcity general throughout the country, and may we attribute it to the same causes as our fruit tree failures? The want of Holly berries is certainly much felt at Christmas time, and if a course could be pointed out which would insure their fruiting annually no doubt many would follow it."

— "THE ARBUTUS UNEDO is one of the freest and finest winter berried trees we have. At the present time its rich-coloured Strawberry-like fruits are hanging in clusters, and contrast well with the little bell-shaped cream-coloured blooms which expand all the year through. In severe winters blackbirds, thrushes, and others destroy many of the berries."

— "RUS" of Reading writes—"Let me recommend BILBERGIA MORELLIANA to your readers. It is a superb plant. Nurserymen do not seem to like it. I had mine from a neighbour."

— THE same correspondent states that OLEANDERS AT PERNAMBUCO are extremely handsome, growing most luxuriantly and flowering profusely, the red and white varieties being highly attractive.

VEGETABLES AT CHISWICK.

A MEETING of the Fruit and Vegetable Committees of the Royal Horticultural Society was held at Chiswick on the 9th inst. (J. Lee, Esq., in the chair), when the following vegetables were examined:—

The collection of Brussels Sprouts growing in the garden was inspected, in all thirty-three lots. A great proportion of these were found to be very much mixed, and also inferior. The following were considered by the Committee the most approved stocks—viz., Aigburth, from Messrs. Kerr; and Otterspool, from Mr. Hinds, which are identical; Dalkeith Improved, from Messrs. Downie and Laird; Cragos Favourite, from Messrs. Cocker & Sons; Scrymgeour's Giant, from Messrs. Nutting; and The Chelsea, from Messrs. Veitch. A new Beet from Messrs. Rutley & Silverlock was examined and highly approved. Some Shallots raised from seed, sent to the garden by Mr. E. Pond of Jersey, were examined. Examples of these when submitted to the Committee at the meeting on October 14th, 1879, were supposed to be Potato Onions, but as now grown in the garden have been found to be true Shallots, the silver-skinned variety being very distinct and pretty. Several new Potatoes grown in the garden were examined, the most promising of which were Carter's New and Lye's Wiltshire Snowflake.

THE WEATHER, AND OUTDOOR GARDENING IN IRELAND.

IRELAND is in more respects than politically a land of contrasts. The late storm and persistent rains were by no means equally diffused. I learn from Mr. Burbidge of the Dublin University Botanic Gardens that it was only by strenuous exertions his staff maintained the fires in the houses where they were indispensable; while the Chief Secretary has inaugurated a subscription for some of the poorer market gardeners and cotters on the banks of the Tolka, Dublin, that overflowed its banks. From Wednesday morning 27th ult. until the following Thursday same hour, 2.736 inches of rain had fallen. For ten years nothing of the kind had been noted, and the greater part of the time a hurricane blew at Kingstown, eighty-five miles an hour being registered. The steady temperature of 46° was during this time maintained there. Turning to the west of Ireland, any of your readers who might contemplate changing to a milder climate warmed by the soft breezes of the Gulf Stream will be charmed with the following extract, by permission, from a letter just received from Mrs. Randal Peyton, Rose Hall House, Sligo, an enthusiastic floral patroness—"The weather here has been so lovely—no storms, no rain: it is a water famine we are suffering from. No mists; nothing but the clearest skies and the most brilliant sunshine.

We have had, however, unfortunately for some half-hardy plants out of doors, too often sharp frosts at night. All the 'American storms' passed over us to break elsewhere. Lough Gill, the beauties of which you so admired, and the rivers here, were never so low within living memory, and the trees are only now in their gorgeous autumn tints. Driving through the country, it is much more like the first week in October; and as we have had no frosts to speak of for the past ten days, though the bright sunshine has continued, I have Roses, Chrysanthemums, Fuchsias, Laurustinus, Anemones, Petunias, Mignonette, &c., all in flower in my garden together, not to mention anything in the greenhouse. We have now nearly completed the planting of our bulbs, including some thousands of Tulips alone, which we were enabled to do uninterruptedly owing to the unprecedented fine weather at this season."

—W. J. M., *Clonmel*.

GLASS STRUCTURES FOR AMATEURS.

OF the many structures employed in gardening, those erected by amateurs present the most diversified aspect. What these are can best be ascertained by an inspection of the numerous examples

to be seen in the vicinity of large towns. Ostensibly constructed for the growth of plants, some are a medley of masonry, wood-work, and glass, the latter quite out of all proportion to the former. The amateur's success with such means is, as might be expected, moderate, yet his attempt to grow plants affords him pleasure and recreative employment. Such structures are often the outcome of a taste engendered by the gift of a few cuttings, which are carefully reared and tended until they outgrow the space afforded by the windows of rooms, and then a greenhouse becomes necessary, and is forthwith erected. Success attends the effort; the windows of the dwelling are full of flowers, the home is made cheerful, passers-by admire it, and thus the taste for flowers spreads, and the means for growing them increase. Many structures are erected hastily, and without due consideration having been given to their suitability for the purpose for which they were intended: failure results and inquiry follows.

That inquiries on the subject in question are prevalent now I have the best proof, for by the same post three letters were sent to me by the Editors. A correspondent living near a large manufacturing town writes:—"I am desirous of constructing a house in which to grow Vines—*i.e.*, Grapes and plants. What descrip-

Fig. 84.—LEAN-TO HOUSE—SECTION AND END ELEVATION.

Scale, three-sixteenths of an inch to a foot.

tion of house would be most suitable? Hints as to making border, selection of varieties, and heating the house would be thankfully received by one in fog, smut, and dust." Next a country curate asks—"Could you give me information in respect of the management of a greenhouse (with Vines) in winter, temperature, watering, ventilation, and general treatment through the winter?" The concluding letter is from a "man of small means:"—"What plants are suitable for growing in a vinery to afford a display of flowers, and for cutting in autumn, winter, and spring? I have no other house, only a few frames. In summer I have flowers from outdoor plants, so that summer-flowering plants are not required for the house, besides I find they do not do well under the Vines at that time; but I suppose the space on the stages might be utilised for growing Tomatoes, Cucumbers, and probably Melons. If you could add (say in an article by one of your many able contributors) a few cultural directions, they would be useful to many others in like circumstances to myself." Accompanying these letters was the following true editorial note, brief and to the point:—"Many have but one house for Vines and plants. Will you write an article on the subject? It would be acceptable to many readers. We have other letters upon the same subject." I

will endeavour to comply, founding my remarks on observations and experience, and will try to conform with the wishes of those correspondents in the hope of being useful to them and others.

Glass structures admit of two forms only—viz., lean-to roof and span roof, the lines being straight or curvilinear; but there are modifications, one of the most important being the half-span. The lean-to is the most eligible where there is a wall already available, especially if it be the blank wall of a building with suitable aspect; but if the wall be not that of a building, or higher than 9 feet, the half-span is preferable, and where there is no wall at all the span roof is the most suitable. I will endeavour to elucidate the matter by illustration so that each may select the form most suitable to his exigency, commencing with a lean-to house for Vines and plants.

References to lean-to section (fig. 84), and ground plan (fig. 85). A, Vine border; B, rubble; C, drain; D, pillars to carry arches of front wall to allow Vine roots to pass out; E, front shelf; F, pathway; G, steps; H, back stage; I, hot-water pipes, 4 inches; J, opening to allow Vine roots to pass into outside border; K, front lights to open entire length of house with crank and lever apparatus; L, top lights to open full length of house with crank

and lever; M, stays for trellis wires for Vines, one stay to each rafter, and wires 9 inches apart; N, boiler (saddle); O, ashpit; P, stovehole; Q, feed cistern; R, boiler flue; S, potting shed; T, skylight; U, potting bench; V, Mushroom bed with bin under to force Rhubarb, Seakale, and Chicory—viz., W; X, fruit room, &c.; Y, propagating bed, rubble over pipes, and covered with frame for striking cuttings, &c. Small jets may be added at one or both ends of the house if required. These frame-like pits cost little and are very useful; they may be readily heated by 2-inch pipes connected with the flow and return pipes in the house, with valves attached to turn on and shut off the heat as required.—G. ABBEY.

CLONMEL DISTRICT ROOT AND FRUIT SHOW.

SOME special features at this fine autumn Exhibition deserve notice. Finer roots, especially of Swede and Long Red Mangolds,

the Judges (Messrs. Fennessy, Waterford, and Freeman, Cahir) admitted they had not seen this year, especially in the competition for the prizes given by Messrs. Sutton & Sons of Reading; but your readers will be more interested in hearing of the fruit and vegetable exhibits. Not only in England, judging from the reports in the Journal and other publications, but in Ireland, the crops of Peaches, Pears, Apples, and other wall fruit are very poor this year; yet the exhibits of Grapes, Pears, and Apples astonished most of the visitors. The first-prize collection of fruit was from Mrs. Bianconi, Longfield, Cashel (gardener, Mr. Palmer). Among the most noticeable varieties were fine Trebbiano Grapes; Emperor Alexander, Calville Blanche, and Golden Russet Apples; Duchesse d'Angoulême and Beurré d'Amanlis Pears. The second collection, sent by Mrs. Thomas Maleomson, Minella, Clonmel (gardener, Mr. John Crehan), included some superb examples. Lord Suffield Apple was admittedly the finest ever shown here. Equally fine was Doyenné Boussoch Pear, which received the first

Fig. 85.—LEAN-TO HOUSE—GROUND PLAN.
Scale, three-sixteenths of an inch to a foot.

prize in its section. Those two dishes were noted by the Judges in a large competition as the best in the Show. Almost equally remarkable were the Apples Hawthornden, Blenheim Orange, Alfriston, and Warner's King; in fact, I noticed in gardens around here whenever any Apple succeeded this year it generally was one of those named. Pears in this collection, too, were very fine, especially Duchesse d'Angoulême and Beurré Diel, while Mr. Crehan's Black Hamburg Grapes were very large and well coloured. Some fine Apples and Pears in the dessert and baking sections were also shown by Lord Donoghmore (gardener, Mr. Ryan), which were awarded prizes. A collection of fruit, too, that deservedly received much admiration were sent in three artistic baskets by Mrs. Crean, Glenview, near this town, representing upwards of a dozen excellent varieties of Apples, conspicuous among which were Alfriston (the largest Apple in the Show), Mère

de Ménage, King of the Pippins, Mannington's Pearmain, and the French Crab, which has been found to remain sound for two years. Catillae, Gansel's Bergamot, and Duchesse d'Angoulême were among the finest Pears. Though this collection was marked "not for competition," the Judges warmly recommended a special first prize. The gardener is Mr. Denis Ryan. The vegetable collections, as at all times, were most commendable. Lord Lismore's, though marked "not for competition," were specially commended for a first prize. It contained Williams' Matchless Celery, white and pink; Bedfordshire Champion Onion, Beauty of Hebron Potato, fine Endive, Mushrooms, and at this time of year admirable Asparagus. The first-prize collection was Lord Donoghmore's, with many novel well-grown vegetables, including the largest Cabbage in the Show, Turnip Beet, Salsafy, Capsicum, Egg Plants, and table Maize. Lady Margaret Charteris had some commend-

able exhibits from Cahir, while the Castletown collection from Col. Villiers Stuart was awarded a special first prize. Other features of this Exhibition were Mrs. Bagwell's splendid floral table decoration design, the large collection of Coniferae and ornamental evergreens from the Clonmel nurseries, and the collections of Potatoes and Gourds, numbering eighteen varieties, from Lord Donoghmore's, Knocklofty. Much credit is due to the courteous and energetic Hon. Secretary, Rev. James Millington, Rector of Kilronan, for the success achieved this year in spite of many difficulties.—W. J. M., *Clonmel*.

ROYAL HORTICULTURAL SOCIETY.

NOVEMBER 16TH.

SELDOM has the November meeting of this Society been fuller and more interesting than the one on Tuesday last. Both the Fruit and Floral Committees had ample employment, but the former especially, while the vegetables staged in competition for Messrs. Suttons' and Hooper's prizes produced an extensive display in the vestibule.

FRUIT COMMITTEE.—Henry Webb, Esq., in the chair. Mr. Maw, Severn House, Handbridge, Salop, sent a seedling Apple which did not possess any distinctive quality. Messrs. Saltmarsh & Son, Chelmsford, sent a seedling Apple called "The Queen," a large, round, and somewhat oblate-shaped Apple, highly coloured and striped. It had a resemblance to Cox's Pomona. The flesh was tender and brisk, with good cooking properties, and was awarded a first-class certificate. They also sent Beauty of Essex, another seedling Apple, with a strong acidity. It was considered good, and the Committee desired to see it again accompanied with full particulars as to its origin. Mr. Osborn Daintree of Swavesey Manor, St. Ives, sent a seedling Apple handsome in shape and colour, but it was not thought to be worthy of special mention. Mr. Balchin of Hassocks Gate, Sussex, sent a seedling Apple which was recognised as being Annie Elizabeth, an Apple already in cultivation.

Mr. Thomas Laxton of Bedford sent a seedling Apple called The Schoolmaster. It was raised from seed of an Apple imported from America, and from a branch taken from a bush tree on the Paradise stock; it has the appearance of being a highly prolific variety. It is a cooking Apple, but has also dessert qualities. It was awarded a first-class certificate. Mr. Laxton also sent two seedling Pears which were not ripe.

The Committee passed a resolution that in future no seedling fruits will receive any attention from the Committee unless accompanied with a full statement as to its origin, place of growth, and a certificate that it is known to be a new variety; and in the case of all fruits except Pine Apples six specimens must be exhibited.

Mr. James Brown, The Gardens, Abercainey, Perthshire, sent a small bunch of the Abercainey Seedling Grape, which Mr. Brown says was raised from seed by his father-in-law forty years ago. It is therefore not identical with Gros Guillaume, but the Committee consider there is so close a resemblance between them as to be undistinguishable. Rev. A. Matthews, Yumley, Market Harborough, sent a seedling green-flesh Melon which was not equal to others in cultivation. Mr. R. Gilbert, Burghley Gardens, Stamford, sent a brace of Montrose Seedling Cucumber, which was considered similar to Telegraph. He also sent a bunch of Trebbiano and Black Alicante in very good condition, to which a letter of thanks was awarded.

Mr. W. Finlay, The Gardens, Wroxton Abbey, Banbury, sent a seedling Onion, the result of a cross between Improved White Spanish and Williams' Magnum Bonum. It was considered a fine Onion, but not an improvement on Magnum Bonum. A letter of thanks was awarded. Messrs. Backhouse & Son of York sent a seedling Onion, which was considered too much like Red Spanish to be distinct.

Mr. Barron sent from the Society's Gardens at Chiswick bunches of Gros Colman, Aluwick Seedling, and Alicante, all of which were grown in the glass wall. They were very fine, and a cultural commendation was awarded.

Mr. Wilson, gardener to Lord Fortescue at South Molton, sent eight handsome Smooth Cayenne Pines, weighing in the aggregate 59½ lbs., to which a cultural commendation was deservedly awarded, Mr. Wilson having previously had a medal.

Mr. Atkins, gardener to Colonel Loyd Lindsay, Lockinge Park, Wantage, sent six handsome bunches of White Muscat of Alexandria, three of Alicante, and three of Black Hamburg Grapes, all very fine, and to which a cultural commendation was awarded. He also sent a collection of twenty dishes of Apples, which also received a cultural commendation. Mr. Charles Ross, Welford Park, Newbury, sent three Smooth-leaved Cayenne Pine Apples, to which a letter of thanks was awarded, and also a collection of six dishes of Apples, six of Pears, six of kitchen Apples, to which a cultural commendation was awarded.

Messrs. Veitch & Sons exhibited a new Potato called St. Patrick, said to be a very heavy cropper, 4 lbs. having produced 236 lbs.; 3 lbs. 180 lbs.; and two tubers 100 lbs. Messrs. Charles Lee & Son, Hammersmith, sent a collection of sixty varieties of Potatoes. It included one called Defiance, a very long red kidney-shaped variety.

Messrs. Sutton & Sons of Reading sent a large collection of Potatoes, to which a vote of thanks was awarded. Also a similar award was given to Messrs. James Carter & Co. for Potatoes and other vegetables. The collections are referred to below.

FLORAL COMMITTEE.—Dr. Denny in the chair; there being a very large attendance of the Committee. Although the plants in the Council-room were not unusually numerous, the tables were completely filled; the brightness of colour was remarkably fine, and the general excellence of the exhibits notable. The most striking collection was that immediately facing the entrance, from Mr. H. Cannell of Swanley, who contributed stands of Salvias, Pelargoniums, and Primula blooms in extremely fine condition. Of these the Salvias attracted by far the largest share of attention, and worthily, for rarely are such brilliant and effective examples staged. The rich blue *Salvia Pitcheri* was excellent, but as it is referred to in another column it does not require description here except to recommend it to the attention of cultivators generally who desire a useful plant for the greenhouse at this time of year; and the same may be said of the others noted below, which are already moderately well known and appreciated. *Salvia splendens Bruantii* is a fine contrast to *S. Pitcheri*, the long corollas, gaping calyxes, and bracts being of a most brilliant scarlet hue. *Salvia Bethelli* has its bright rosy purple flowers thickly clustered in whorls on the upper part of the branches, with a peculiar terminal and spherical bud of the same colour. Another one was shown under the name of *S. pseudo-coccinea*, with a rather lax inflorescence and comparatively small crimson flowers. Double Zonal Pelargoniums were also fine, some of the most effective being Mr. Henry Cannell, a good scarlet; *Nympha*, white; Eugene Bandouin, pink; and *Sylvia*, pink. Trusses of Pelargonium *Beauté de Lyon* were sent in fine condition, and flowers of Mr. Cannell's strain of Primulas, including several good shades of colour. A vote of thanks was accorded.

Messrs. Veitch & Sons, Chelsea, exhibited flowers of two fine Pompon Chrysanthemums—Maiden's Blush, white with a faint lilac tinge, and Purple Pompon, good form and colour. A specimen of *Dendrobium phillipinense* with a long growth, bearing about two dozen of its faintly coloured yellow flowers, the pointed labellum of a deeper shade and streaked with maroon. A small specimen of *Cypripedium Fairianum* was shown with a single flower, the two petals hairy on the back and margined with deep purple, the upper sepal similarly streaked and the edge undulated, the labellum being small and green. Mr. R. Gilbert of Burghley sent several profusely flowered double Primulas—White Lady, having large, well-formed, pure white flowers; Mrs. A. F. Barron, white, streaked, and tinged with pink; Lord Beaconsfield, a deep fleshy pink, very large flower, white beneath; and Marchioness of Exeter, similar to Mrs. A. F. Barron.

Messrs. Osborn & Sons, Fulham, sent a box of blooms of Gilbert's double Primulas, the trusses being unusually large. Messrs. Carter and Co., Holborn, exhibited a plant of *Griffinia hyacinthina maxima*, a pretty Amaryllidaceous plant flowering without its leaves, and bearing an umbellate scape of white and purplish-blue flowers. Mr. J. King, gardener to G. Simpson, Esq., Wray Park, Reigate, contributed several Coleuses, Mr. John Baxter being very brightly coloured. Mr. H. B. Smith of Ealing staged considerably over a hundred healthy plants of Cyclamen in 48-pots, the foliage large and finely marbled, the flowers numerous, excellent in form and colour, the crimsons and whites being particularly noteworthy. The handsome white variety Mont Blanc, certificated by the Royal Horticultural Society in 1878, was also shown with specimens of Rosy Morn, awarded a similar honour in the same year.

Messrs. Paul & Son, Waltham Cross, had a Primula with variegated foliage, and one with very large white flowers, named Waltham White. Messrs. E. G. Henderson & Son, St. John's Wood, sent a seedling Primula named Duke of Edinburgh, not particularly distinct, though the flowers were of fair form. Mr. C. J. Salter, gardener to J. Southgate, Esq., Selborne, Streatham, submitted a flower of the Chrysanthemum Lady Selborne, the beautiful white sport from James Salter, described in another column. The Committee, while admiring it, would not award it a certificate until they have seen more flowers or a plant. An assumed hybrid Fern was shown by Mr. J. P. Kendall, gardener to H. L. Holland, Esq., Templeton, Roehampton; it was named *Pteris Prattiana*, being said to be a cross between *P. tremula* and *P. serrulata*, the fronds appearing to partake of the characters of both, but larger in size. Mr. W. Kipps, gardener to John Crossfield, Esq., Walton Lea, Warrington, had flowers of an incurved Chrysanthemum named Mrs. John Crossfield, of a faint lilac tint, but not considered sufficiently distinct to merit a certificate. From the Society's garden a number of fine single Primulas, all varieties of *P. sinensis* and *fimbriata*, were sent; among them the following were particularly fine:—*Rubra violacea*, *lilacina marginata*, Chiswick red, alba, and carmine. Messrs. C. Lee & Son, Hammersmith, sent plants of the Japanese Chrysanthemums Mons. Crousse and Clythe, with a Pompon named Sanguineum, but they were all passed. Messrs. Smith and Larke were accorded a vote of thanks for two handsome bouquets of white, yellow, and red Chrysanthemum blooms, very pretty and effective.

First-class certificates were awarded for the following plants:—

Salvia Pitcheri, *S. splendens Bruantii*, and *S. Bethelli* (Cannell).—A trio of handsome Salvias already described, and for greenhouse decoration at this time of year they can scarcely be excelled. The rich blue of the *S. Pitcheri*, the intense scarlet of *S. splendens Bruantii*, and the soft rosy purple of *S. Bethelli* are three fine distinct colours, and in combination with the free growth of the plants and their floriferousness are sufficient to recommend them to all.

Bouvardia Dazzler (W. Balchin, Hassocks Gate, Sussex).—An

attractive and floriferous variety of vigorous habit, bearing fine clusters of moderately large flowers, the limb of which is a deep scarlet, and the tube of a rosy tint.

Cypripedium Fairrieanum (Veitch).—A small but pretty form of Lady's Slipper, already described.

SCIENTIFIC COMMITTEE.—Hon. and Rev. J. T. Boscawen exhibited a female branch of the inflorescence of *Chamaerops Fortunei* or *excelsa*, and remarked that the male panicle had previously appeared and fertilised a plant at some considerable distance. Dr. Masters exhibited the erect form of *Ficus repens* bearing fruit from Mr. Mitchell Henry's garden at Galway. He also exhibited a spike of female blossoms of an American Chestnut, *Castanea pumila* (?), occupying the place of the male flowers; and a remarkable fasciated specimen of a species of *Casuarina* from Baron Von Müller, Spruce and Ash branches in a fasciated condition, as well as a branch of Larch bearing tuft-like branches resembling some Brazilian Firs.

Mr. McLachlan reported on some diseased Oranges and Lemons, which were attacked with the *Aspidiotus coccinus*, sent by Mr. J. L. Giustiniani, Manchester. It was suggested by him that, although no cause could be assigned for the attack, sulphur or else "stamping out" would be the best remedy. Col. Clarke suggested the use of paraffin oil (one tumblerful of old lamp oil mixed with one bucketful of water and syringed). Mr. Boscawen suggested methylated spirit, one pint; soft soap, 3 to 4 lbs.; and 1 or 2 ozs. of camphor, as a good remedy. He also exhibited specimens of *Componotus inflatus* (Lubbock) ant, described by Sir John Lubbock, from South Australia. They appear to be workers which remain inside the nest, while other ants bring them honey. This they subsequently retail to the others as it is required. They are, in fact, "animated honey pots." He also exhibited the remarkably horned *Eucalyptus* Galls figured and described in the *Gardeners' Chronicle* a short time ago.

Mr. Boscawen exhibited specimens of *Odontoglossum Alexandræ* with the bud eaten by a maggot. Mr. McLachlan suggested that it possibly might be a *Curculio*. The maggot itself had been attacked by some parasitic Hymenopterous insect. Mr. Boscawen also exhibited *Rhododendron* leaves curiously eaten at the edges. They were lower leaves, and the general opinion seemed to be that it was due to slugs. Mr. G. F. Wilson alluded to the injury caused by galvanised wire, probably inefficiently galvanised, and said he found it to be a firm belief amongst horticulturists that the injury of rotting the wood was due to the wire. If well painted no injury ensued. Mr. W. G. Smith exhibited specimens of the fungus *Geaster rufescens* from Mr. T. Clarke, Shadwell Court, Thetford; and Pine wood eaten by some larva, showing how the animal had avoided the harder tissues, as knots, &c.

SPECIAL PRIZES FOR VEGETABLES.

On this occasion prizes were offered by Messrs. Sutton & Sons, Reading, and Messrs. Hooper & Co., Covent Garden, London, for collections of vegetables and also for single dishes of Potatoes, and in response thereto many fine collections were brought from many parts of the country. For the prizes offered by the former firm for a collection of twelve distinct kinds of vegetables there were fourteen competitors, the majority of whom staged really excellent produce. The first prize, after a long and careful scrutiny by the Judges, was awarded to Mr. J. Austen, Ashton Court Gardens, Bristol, for a generally excellent collection, consisting of Telegraph Cucumbers, Orangefield Tomatoes, Leicester Red Celery, Nutting's Dwarf Red Beet, James' Intermediate Carrots, Canadian Wonder Beans, Lapstone Kidney Potatoes, Veitch's Self-protecting Cauliflower, and Imported Brussels Sprouts. Mr. J. Roberts, gardener to the Baroness de Rothschild, Gunnersbury Park, Acton, secured the second prize; the third going to Mr. J. Muir, gardener to C. R. M. Talbot, Esq., Margam Park, South Wales; the fourth to Mr. W. Iggulden, Orsett Hall Gardens, Romford; and the fifth to Mr. S. Haines, gardener to the Earl of Radnor, Coleshill House, Berks—all following each other closely with their respective exhibits. Mr. Roberts' best dishes were Tender and True Cucumbers, Hepper's Goliath Tomatoes, Snowball Turnips, and Horn Carrots. Mr. Muir's collection comprised a good dish of Crossling's Glamorgan Tomatoes, good Carter's Jersey Lily Turnips, Suttons' King of the Cauliflowers, and Gilbert's Cabbage Broccoli, shown in this instance as a Cabbage. Mr. Iggulden staged good examples of Major Clarke's Solid Red Celery, Snowflake Potatoes, and Veitch's Autumn Giant Cauliflowers. Mr. Haines showed good Trophy Tomatoes, and Suttons' Improved Reading Onions. The Brussels Sprouts were shown throughout as growing, and were a prominent feature in the display.

Onions.—There were twelve dishes of Suttons' Improved Reading Onions staged, the first prize going to Mr. J. Austen for very fine examples; the second to Mr. J. Lye, Cliffe House Gardens, Devizes; and the third to Mr. S. Haines, both staging heavy specimens.

Potatoes.—Twenty-seven dishes of Suttons' Magnum Bonum were staged, the three prizes going to Mr. J. Howard, Bridge, Canterbury; Mr. F. Miller, Northdown, Margate; and Mr. G. J. W. Andrews, Dorchester, in the order named, all staging very fine examples of this popular variety. Only six dishes of Suttons' Reading Abbey were staged, the best being from Mr. W. Meads, gardener to Viscount Barrington, Beckett Park, Shrivenham; the second prize going to Mr. W. Iggulden; and the third to Mr. J. Phillips, gardener to Captain Jackson, Meopham, all staging creditably. Of Suttons' Woodstock

Kidney there were thirteen dishes staged, the first prize being awarded to Mr. W. Iggulden for rather small but clean and well-shaped tubers; the second prize going to Mr. R. Phillips, and the third to Mr. C. Ross, Welford Park, Newbury. Several fine dishes were staged, which, however, were passed on account of being greened by exposure at a previous show.

Messrs. Hooper & Co. offered prizes for the Beauty of Kent Potato, and for these there were five competitors. Messrs. C. Ross, W. Iggulden, and R. Phillips received the awards in the order named, all staging good examples of this superior-looking Potato. For the prizes given for a collection of nine dishes of vegetables, to include Hooper's Acme Tomato, Hooper's Market Favourite Onion, Beauty of Kent and Pride of America Potatoes, there were only two competitors. Mr. R. Phillips was awarded the first prize for a collection which, in addition to good examples of the stipulated varieties, comprised good selected Brussels Sprouts, Musselburgh Leeks, Canadian Wonder Beans, James's Intermediate Carrots, and Autumn Giant Cauliflower. Mr. W. Iggulden secured the second prize for a collection slightly inferior.

A TABLE running through the whole length of the vestibule was filled by Messrs. Carter & Co., London, with an assortment of well-grown vegetables, among which several of their novelties were well represented, and nearly a hundred varieties of Potatoes. Very prominent among the former were some fine examples of Carter's Ruby Tomato, an extremely bright red variety of fair size and good shape; Carter's Jersey Lily Turnip, a good type of the Snowball; Carter's Perfection Beet, Carter's Incomparable Crimson Celery, and a number of Kales and Savoys. Of Potatoes they exhibited fine heaps of Carter's Improved Magnum Bonum, Carter's select stock of Scotch Champion that were grown at Sandringham. The general collection comprised good examples of the new Wormleighton Seedling, Edgott Seedling, Porter's Excelsior, Purple Ashleaf, Blanchard, Beauty of Kent, and the new Early Eight-weeks.

Messrs. Sutton & Sons likewise staged fine heaps of Potatoes, the most prominent being Suttons' Magnum Bonum, Suttons' Woodstock Kidney, Suttons' Reading Abbey, Suttons' Redskin Flourball, and Schoolmaster. In addition they had good dishes of all the leading varieties, including Fox's Seedling, Triumph, Covent Garden Perfection, Rector of Woodstock, Red Ashleaf, Snowflake, Early Hammer-smith, Vicar of Laleham, Lye's Favourite, St. Patrick, Porter's Excelsior, Red Fluke, Bedford Prolific, and Bresee's Peerless. Messrs. Suttons also staged fourteen seedling Potatoes, among which were several raised by Mr. R. Fenn that have passed into their hands. Some of them were of very promising appearance, and are said to be good disease-resisters.

LECTURE ON THE CHRYSANTHEMUM.

THE following is the substance of the Rev. G. Henslow's lecture on the Chrysanthemum, delivered at the above meeting. The lecturer called attention to some of the more important species in cultivation—viz., *C. segetum*, the Corn Marigold of our fields, was cultivated early in the eighteenth century with both single and double varieties; the Ox-eye Daisy being another British species, *C. leucanthemum*. Of foreign kinds *C. coronarium*, the "Garland Daisy," is said to be a culinary vegetable in China. *C. frutescens*, from the Canaries, with yellow and white varieties, is the Marguerite of the French; the principal species of garden Chrysanthemums being *C. sinense*, *Sabine*, and *C. indicum*, *Linn*, or the "Chusan Daisy" of Japan.

The first notice of the cultivation of *C. sinense* in Europe appears to be of those grown by Jacob Breyn in 1688 at Dantzic, who had "bright rose, snow white, purple, dull yellow, flesh-coloured, and crimson" varieties. A plant of *C. indicum* was in the Chelsea Gardens in 1764, but was soon lost. M. Blaneard had three forms, a white, purple, and violet, growing at Marseilles in 1789, and from thence Mr. Colville of King's Road, Chelsea, grew a dark purple semi-double form in 1795. This appears to have been its first introduction into England. Yellow and other colours were introduced in 1802 and following years till ten varieties were grown in 1808. They increased to forty in 1827. In 1846 Mr. Fortune introduced the Chusan Daisy and Chinese minimum form of *C. indicum*, and the origin of the Pompons, for the first successful cultivation of which we are indebted to France. The number of forms then rapidly increased, till in 1860 no less than 750 varieties were growing in a single garden!

Mr. Fortune in 1860 collected several curious forms from the Japanese gardens. He left them at Shanghai while he went to Peking. On his return he found all were dead but two or three. These reached Mr. Salter of Hammersmith, who raised from seed varieties which proved to be identical with those Mr. Fortune had lost. Chrysanthemums have been long cultivated in Japan and China, and it is said that he who can produce the largest flower bestows most honour on his guest. One variety is called the "Drunken Woman," as it has small pendulous flowers in the morning and evening, but which are erect during the day. In the gardens at Yeddo imitation ladies are built up of these flowers.

With the regard to the origin of the variations, they are due to changes undergone by the disk or centre florets, naturally tubular with a regular border, for the wild original forms were not larger than a sixpence, and with "ray" and "disk." When a disk floret becomes like a ray floret it not only enlarges but suppresses two

petals and splits all the way down, so that the "ligulate" or strap-shaped florets have only three petals. When they are rather broad they give rise to the incurved and reflexed forms, according as they show the under or upper side of the florets. When they are narrow the flower resembles the Japanese original form with slender tapering petals. On the other hand, if the tube elongates without much splitting we get the tasselled, quilled, and Dragon forms. In the first the tube splits only for a short distance into a broad flat piece at the end, in the second the border is reduced, but in the third enormously enlarged with the teeth increased in number. This last resembles the ray florets of the Cornflower, which is much enlarged under cultivation, and has its teeth increased in number also.

WINTER PROTECTORS.

If plants and crops which are liable to be injured by frost or severe weather have not already been covered up, or provision made for doing so directly it is required, no time should now be lost in making the necessary arrangements. At one time we were not very particular about this, as we could almost depend on being without severe frost to nearly the end of the year; but times have changed, and protectors are wanted frequently as early as October, and we can hardly be said to be independent of them for at least six months in the year. Mats, woollen and other cloths, straw, hay, leaves, fern, and ashes, are some of the materials which may be used for protecting, and a good store of one or all should be at command according to the extent of covering to be done. Vegetables are not the least important of the crops to be protected. I am annually gaining knowledge and experience in the kitchen garden, and the impression is increased that if any gardener wishes to do credit to himself and give the highest satisfaction to his employer, the vegetable supply must be unlimited. There are a few, but very few, who have no demand on them in winter for vegetables, but the demand upon the majority is greater at that time, and, therefore, protecting the crops so as to retain their high qualities and the quantity as well, is of the utmost importance.

A good root shed is an actual necessity in all gardens. It may not be warmed artificially, but it should have a waterproof roof, and protectors should be used inside when necessary to exclude severe frost. Parsnips, Salsafy, and other roots are often left in the ground for the greater part of the winter. They keep very well under these circumstances, but they are better if covered to the depth of a few inches with coal ashes, short straw, hay, or leaves during severe frost; and it is very convenient if a number of them are lifted before the ground becomes frozen very hard and stored in the root shed for use. Besides this being very handy, it is satisfactory in many ways; as although Parsnips, Salsafy, and Turnips come all right again when thawed after being frozen, they are not by any means so good when taken and thawed quickly immediately before cooking.

Celery is another valuable winter crop, and it is also easily injured by frost. It is important to have it thoroughly protected early, because if once affected by frost it will fail to keep well afterwards, although the weather may become mild. A quantity of straw or fern placed closely round the neck of each plant and a little thrown over the top will be useful, but if more effectual protection can be employed so much the better. I have lately had a number of wood covers made that are excellent for protecting Celery. They are of various sizes, and resemble in shape little span-roofed houses. The great benefit of these is, that while they keep out much frost they allow no wet or snow to rest on the plants they cover; and this is a great advantage, as so long as the leaves can be kept dry little loss will occur. Parsley, Spinach, and Celery may be protected by these wood covers. Cauliflower, Brussels Sprouts, Savoy, and other greens also need protecting, especially the first named. It is a good plan to examine the plants once or twice a week, and tie the leaves over the heads. Those large enough to cut may be lifted and placed close together in the root shed, or the heads may be cut off with a little of the stem attached, and by inserting this in damp sand in the root shed the head will remain good for some weeks.

Lettuce and Endive must also be protected. If lifted now and placed in dry frames few will be lost. A flower pot inverted over each plant is also a good mode of protecting the plants from frost. Rhubarb, Seakale, and Asparagus should be covered over to the depth of a few inches with some manure. Plants in frames should be kept dry in the leaves, and plenty of straw or fern should be thrown over the frames in severe weather. Cuttings of Calceolarias and Pansies in beds near walls must have the same attention. Small shrubs of a tender character can be drawn together, tied, and then thatched round with straw or old mats. Any tender bush against a wall should be served in the same way. Bulbs and roots in the ground which may be injured by frost may be covered over with decayed manure. This is better for most

plants than ashes. Fruit trees, Rose bushes, and all that have been lately transplanted may have a layer of manure over the roots. Glass houses are rarely protected outside. The greater the cold the more the fire heat employed; but outside protectors might also be advantageously used in various ways. I especially refer to the large houses, on many of which in summer the shading material is on rollers; but they are all taken away in winter, though in many instances I think they might be of more advantage in winter than summer, especially if a good thick material were employed. I have found a good covering outside during frost and snow keeps the temperature up better than nightly consuming an extra hundredweight or two of coal.—A KITCHEN GARDENER.

KITCHEN GARDEN.

THE present is a good time to effect any improvement in the various soils, especially those of a stiff adhesive character, which should be placed in ridges in order that as large a surface as possible may be exposed to atmospheric influence. Such soils will be permanently improved by the addition of ashes, charred vegetable refuse, and an occasional dressing of lime. Forking over heavy soils on dry frosty mornings is a capital means of pulverising them and securing a good tilth, but working during wet weather must not be practised. Light soils are not so much benefited by exposure, but no opportunity must be lost of improving them by the addition of such materials as marl, clay, or lime. Trenching is an important operation, and should always be performed with judgment, as to bring up a subsoil of clay or the "brash" of light or gravelly soil does not add to their fertility. After throwing up the good soil loosen that beneath with a pick, and leave it there for a time, bringing up a little at each subsequent trenching, increasing the depth of soil by stirring. In some very light soils winter digging is not advisable, except as a means of destroying annual weeds.

Forcing Department.—In order to obtain a liberal supply of forced vegetables active operations will now be imperative; and if such as Asparagus, Seakale, and Rhubarb have had their growths early developed and matured, the crowns will break freely and strongly with less forcing, and the produce will be finer. Early forcing is best effected by subjecting the plants to the heat of fermenting materials, especially in the case of Asparagus. Seakale, Rhubarb, and Chicory also succeed very well in the Mushroom house. For Asparagus pits are most suitable, having space for sufficient fermenting materials to maintain a temperature of 70° to 80°, with one or more hot-water pipes for securing top heat in severe weather. The pits must have moveable lights to admit of ventilation at suitable times. Asparagus may also be successfully forced in frames over dung beds. To ensure a supply at Christmas a bed composed of about half stable manure and leaves may now be prepared, rendering it firm and covering with 3 inches depth of light rich soil. When the heat does not exceed 80° nor is less than 70° the roots should be introduced, spreading them out and placing some rich soil amongst them, supplying water at the temperature of the bed, and then covering with 2 or 3 inches of finely sifted spent tan or cocoa-nut fibre refuse. A temperature for the frame or pit of 60° to 65° is suitable. Introduce more roots of Rhubarb and Seakale to the Mushroom house, and where Chicory is employed for salad treat it similarly, placing roots in pots or plant them in rich soil. Supply tepid liquid manure as necessary to crops of the above. French Beans must have a light position and not a close stagnant atmosphere, but avoid cold draughts or the pods will be stunted. Make further occasional sowings according to the demand and space. Sow Mustard and Cress according to the demand. Potato sets for early forcing in pots or beds may be inserted in leaf soil for sprouting preparatory for planting, a moderate heat being necessary to accelerate the process. Dwarf Peas are sometimes forced, but unless ample accommodation is at command in a light airy structure the return is not very satisfac-

tory. Blue Peter, Little Gem, and Early Premium Gem are best for the purpose. They may be grown in boxes or pots. Where forcing is extensively carried on it is important to have a good supply of fermenting materials ready for immediate use, and now that leaves are obtainable this must not be neglected. Whenever the weather is favourable freely ventilate the frames containing Lettuces, Endive, Parsley, Cauliflowers, and Radishes, having the requisite protective materials at hand for prompt application in severe weather, but employ them only to exclude frost, for the hardier the plants are kept the safer they will pass the winter.

FRUIT HOUSES.

Vines.—Early and permanently planted Vines which are expected to furnish ripe Grapes by the end of May should have the final dressing, especially if there have been any scale or mealy bug, and whatever is necessary in the way of repairing or cleansing the house must be completed at once. The house should be closed at the beginning of next month, and to economise fire heat and secure a moist genial atmosphere a good bed of leaves and stable manure in about equal proportions may be placed upon the borders and turned over at short intervals, adding fresh material as the heat decreases. Old Vines that have been forced some years start readily, but young Vines do not break so quickly, and should be started about a fortnight earlier or at once. The former also require more heat to induce growth, a temperature of 50° to 55° at night being suitable, and 65° in the day from sun heat. Old Vines will break freely and regularly with a temperature of 50° at night, but young Vines will need to have the canes slung in an horizontal position over the fermenting materials until the buds have started. The Vines must be syringed frequently during the day with water 5° to 10° warmer than the atmosphere of the house. Frequently turn over the fermenting material in the earliest house, adding fresh as the heat declines, and for Vines in pots plunged also maintain the heat by additions when needed. The latter may be placed on pedestals of brickwork in the bed. The earliest started Vines in pots may now have the temperature increased a few degrees with advantage, increasing the atmospheric moisture proportionately. Not much ventilation will be necessary, and what is requisite should be given at the top of the house, and if some netting be placed over the ventilators it will prevent the in-rush of cold air.

Ripe thin-skinned Grapes such as Black Hamburgs still hanging cannot be kept too dry, affording moderate heat with liberal ventilation on fine days, maintaining a steady temperature of about 50°. This should be continued until the Vines are leafless, when, if plants have to be wintered in the house or the roof is not as waterproof as might be desirable, the Grapes had better be cut with portions of the stem placed in bottles and conveyed to the Grape room, or they will keep well enough in the house with such late varieties as Lady Downe's. Late Grapes are now ripe or they never will be, nothing being gained by sharp firing to make up any deficiency after the wood is ripe; the additional fire heat will probably only accelerate the shrivelling of the Grapes. If the defective finish be a consequence of overcropping the Vines may be eased by cutting a portion of the crop.

Cherry House.—The lights removed from this structure must be replaced at once. Attend to pruning the trees, but if the shoots were stopped during the season of growth it will only be requisite to shorten those shoots back to about an inch from their base. The terminal shoots should not be cut back unless necessitated by lack of space, or when it is desired to increase the shoots next year. All decayed spurs must be removed. Young trees which are in course of formation will also require to have the central shoot cut back as may be necessary to provide the growths to fill up the allotted space with regularity; the house should then be thoroughly cleaned, and the trees dressed with an insecticide. Train and tie the trees; remove all the loose material from the surface of the border and any inert soil from about the roots, but do not disturb them, finishing with a top-dressing of 2 to 3 inches thickness of good decomposed manure. Ventilate the house freely except during frost. To have ripe fruit early in May the house will need to be closed early in December.

Cucumbers.—Cold easterly winds have necessitated sharp firing

and the exercise of great care in the admission of air, which, whilst a little should be given at every favourable opportunity, it certainly should be excluded as far as practicable when it is brisk and cold. During bright sunshine in such weather turn off the top heat so as to lessen the need for ventilation, and maintain a good amount of moisture; but in dull weather, especially when foggy, be very sparing of moisture. Examine the growths regularly every week in stopping and thinning, removing bad foliage. During severe frosty nights the covering of the lights will lessen the need for sharp firing, and this will prevent the distressing effect of a parching atmosphere, which is never so disastrous as during the night.

Pines.—Strict attention must be given to the ventilation of pits or houses containing young stock, as the plants will soon become weakly. To keep young stock slowly growing temperatures of 60° at night, falling to 55° on cold mornings, and 65° in the daytime, are suitable. At 65° admit a little air at the top of the house or pit, and unless the temperature falls below that point continue the ventilation throughout the day. When by external influence the temperature attains 75° allow a free circulation of air through the house, keeping the plants near to the glass, and allow each plenty of space, maintaining the heat at the roots steady at 80°. Do not have too much moisture in the house, and water the plants whenever they become dry with weak liquid manure. If there is likely to be a deficiency of suckers for starting in spring keep those which are ready now either by detaching and potting them in 5-inch pots, or preferably preserving the suckers on the stools of the plants after the fruit is cut, and place them together in a moist pit near the glass in a bed having slight bottom heat and a temperature of 55° at night, keeping them moderately dry at the roots.

PLANT HOUSES.

Stove.—Gardenias that are desired to flower shortly if well furnished with buds may be placed in a brisk moist heat of 70° in a light position, and not too saturated with water at the roots, or the buds will fall. With sufficient stock the highly fragrant flowers of these plants can be had all the year round, but during the winter they are most acceptable. *G. intermedia* is by far the best variety, the flowers of *G. citriodora* when mounted also being fine for bouquets. Some of the winter-flowering plants—such as Poinsettias, Aphelandras, Centradenias, Eranthemums, Justicias, Plumbagos, Sericographises, Centropogons, Thyrsacanthuses, and winter-flowering Begonias—should be brought gently forward in a temperature of 60° to 65°. Abundance of light is essential; indeed, they cannot be too close to the roof lights, providing they do not touch the glass. The reserve stock of the above intended for successional flowering must not be neglected or allowed to remain where they be chilled and lose their roots, or the flowers will be unsatisfactory. A temperature of 50° to 55° will suit them, giving no more water than is necessary to keep the leaves and roots from being injuriously affected. *Euphorbia jacquiniæflora* must be kept in the lightest position the house affords, or the flowers will be of an orange red colour instead of the fiery scarlet, for which it is so much prized. Where a miscellaneous collection of stove plants have to be accommodated in one house it becomes a difficulty to manage the whole satisfactorily, as some are being brought on for successional flowering during the winter whilst others are at rest. Market growers, who grow but few plants and have houses for each, do them much better than the private grower. Where, however, all have to be placed together a compromise is needed both in heat and moisture, arranging those at rest at the cooler end of the house, and those requiring more heat at the warmer end, using as far as possible the moisture at this end, and not here admitting any air, giving it only at the coolest end. Plants partially deciduous—such as Clerodendrons, Aristolochias, Bougainvilleas, and Allamandas—may be for weeks without water, but the wood must not be allowed to shrivel. Stephanotis should also be kept dormant by dry treatment, yet the leaves must not become very flaccid or they will fall. Evergreen plants, such as Ixoras and Gardenias, must have a sufficient supply of water to keep the foliage in good condition. Ixoras, Dipladenias and Allamandas should never have a lower temperature than 65° at night.

Cyclamens.—Those plants that are now producing their flowers

should be kept near the light in a temperature of 50° artificially, which applies equally to successional plants and seedlings of the current year. Any seedlings in small pots may be shifted, employing good loam with about a fourth of decomposed manure.

Primulas.—These do not thrive in damp cold houses, therefore place them near the glass, and where the temperature is kept at 45° to 50° artificially, in which they will continue flowering all the winter profusely. The double forms are excellent for producing flowers for cutting, as they last much longer than the single varieties. The semi-double varieties are also good for cutting, and have the advantage of being better growers than those which are perfectly double.

Fuchsias.—All of these that have finished blooming should be gradually ripened. Withhold water gradually, so as to keep the wood plump. They may be wintered under open greenhouse stages, or in any light dry spot where they will not be subjected to very severe frosts.

Zonal Pelargoniums.—Plants grown and specially prepared for winter flowering should now be placed where they will receive extra heat, 50° at night, and 55° to 60° by day, whilst those to succeed them must have a temperature of 50°, and be given sufficient water to keep them slowly growing.

TRADE CATALOGUES RECEIVED.

Bruant, Boulevard Saint-Cyprien, Poitiers (Vienne), France.—*Catalogue of Trees and Shrubs.*

James Backhouse & Son, York.—*Catalogue of Trees and Shrubs.*

Oudin, aîné, Liseux (Calvados), France.—*List of Trees and Shrubs.*

* * All correspondence should be directed either to "The Editors" or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Asphalte Tennis Ground (Johnson).—If the site is very wet it is very desirable that it be drained, and the asphalted portion would be more durable.

Osmunda regalis (H. Pierce).—It is not confined to Europe, but has been found near the Himalaya Mountains between Choi and Kot.

Horn Manure (H. F. C.).—We do not know where the above manure is to be had in Scotland.

Culinary Apples (A. B. C.).—The following are six good varieties for succession, being hardy and free bearers:—Keswick Codlin, Cellini, Stirling Castle, Beauty of Kent, Warner's King, and Dumelow's Seedling.

Double Primulas (J. Bartlett).—The flowers sent are very fine, some of them being quite equal to the varieties that have been exhibited by Mr. Gilbert of Burghley.

Mistletoe (G. N.).—It occurs in some parts of India. Mrs. Aynsley states that they found it in the valley of Kashmir growing on the Walnut trees, which there are numerous, the nut being a prominent part of the food of the natives.

Seedling Abutilon (A. J. S.).—The flower is of good form, but there are several varieties quite equal to it in that respect, and some of them of a clear bright yellow colour. Your variety is worth cultivating, but it possesses little or no commercial value.

Growing Seakale (Lobster).—If the district is a dull and showery one you may possibly succeed in growing Seakale on the steep bank facing the sea, especially if you cover the surface of the ground thickly with manure. If the locality is a dry one you cannot expect to obtain large crowns from such poor gravelly soil.

"Herefordshire Pomona" (A. F.).—Three parts of the "Herefordshire Pomona" have appeared. They are published annually, and the price of the first two is 15s. each. The next part, which is larger than the preceding is 21s. The work is expected to be completed in seven parts.

Painting Glass Structures (K. W.).—We do not undertake to supply information on this and kindred subjects that are strictly within the province of tradesmen. A more correct idea of the cost of all such work can be obtained by inviting two or three tradesmen to supply tenders for completing the work than can be afforded through the columns of any journal.

Propagating Palms (L. C. L.).—You will not succeed in propagating your Palm by "dividing it into smaller pieces," and if the specimen has become

too large for table decoration it should be grown on for the stove or greenhouse according to the treatment it requires. Palms are raised from seeds which are imported in large numbers, and generally raised in pans of light soil in bottom heat, but young specimens may be obtained at moderate prices from the chief nurserymen.

Vines in Pots (J. S.).—No variety is equal to the Black Hamburg for fruiting in pots, and we should grow but few of other varieties. Foster's Seedling is one of the best bearers of the white varieties for the same purpose. The Frontiguans are suitable for pot culture; the bunches are not large, but the flavour of the fruit is excellent. The Primavis Frontignan, Tokay Frontignan, and the Early Auvergne Frontignan are good varieties; you had better, however, rely chiefly on the Black Hamburg. From five to ten bunches, according to their size, may be retained on each Vine. The leading growth should be stopped at five or six leaves beyond the bunch.

Raising Seedling Briars (J. H. W.).—You may sow the seeds now thinly in drills a foot apart, covering them with light soil containing a good proportion of wood ashes. The whole of the seed will not germinate the first year, therefore the ground must always be kept scrupulously free from weeds. When large enough the seedlings may be transplanted 6 or 8 inches apart in rows 18 inches asunder, there to remain and be budded. The seed beds must be kept quite free from weeds, and the seedlings may be transplanted as soon as they have shed their leaves in the autumn or in early spring.

Striped Double Stock (L. M. N., Dublin).—The flowers are attractively flaked with purple on a white ground like a rose flake Carnation. The growth resembles that of the East Lothian Stock, but is insufficient for us to determine the point. Unless you have single flowers similarly striped you will not be able to perpetuate the variety. We have seen flowers of the German Ten-week Stock striped, but not quite so clearly as those before us. If you show a flowering branch to Mr. F. W. Burbidge, the Curator of Trinity College Botanic Gardens, he will be sure to have something to say worth hearing on the sportiveness of flowers.

Narcissus Bulbocodium in Pots (R. D. G.).—Bulbs of various kinds that are potted and flowered in greenhouses very frequently produce tall, thin, and imperfect foliage owing to the plants being placed at some distance from the glass and probably crowded; they cannot then obtain the light and air necessary for producing healthy foliage, without which flowers the following year cannot be expected. Too often also after bulbs have flowered the pots are placed in the most unlikely of positions for the full development and maturation of the foliage of the plants. If the same care were bestowed on the plants after they have flowered as before, they would be in much better condition for flowering a second year than is the case under the treatment to which they are generally subjected.

Old Vine not Bearing (Midland Counties).—Vines so old as yours are not infrequently cease bearing out of doors when pruned on the spur system. As you are unable to apply manure to the roots to impart fresh vigour to the Vine we advise you to cut out every alternate vertical rod nearly close to the horizontal main, and near a bold eye or bud if possible; fresh growths would start, and the strongest could be selected and trained up the wall in place of the rods removed, these young canes only being shortened at the winter pruning to the extent of removing the immature portion. Another year, or when you desire it, the remaining rods can be removed, and so your wall may be covered with young canes without wholly divesting it of the Vines, which might be objectionable. Vines on walls usually bear the best crops when the old roots are systematically removed, young canes trained up, and all the growth retained that is hard, brown, and firm; in a word, we think if you substitute the long-rod for the short-spur mode of pruning your chance will be very much greater of obtaining fruit. If the Vine does not bear when so treated you may conclude it is either worn out or the variety is unsuitable for outdoor culture.

Vines Overcrowded (J. E.).—Two rods will be quite sufficient in the space you name; in fact, there is not properly room for two unless the spurs are very thinly placed on them. Cut out the old rod and remove a number of the weaker spurs from the others, so that those remaining are about 15 inches apart. The spurs may be removed at once with a small toothed saw, paring the cuts smoothly with a sharp knife, and dressing them with lead-coloured paint. You have done quite right by training up a young cane from the base of the other Vine. The old rod may either be cut out entirely or have all the spurs removed from the lower portion as far as the young cane reaches after it is pruned, or a little farther. A length of about 4 feet will probably be sufficient for the young cane; and if the buds or eyes on this are numerous, the young growths can be thinned out in spring when they are an inch or two in length, retaining those that are the most promising and which show the best bunches. It is no trouble to us to reply to questions on gardening when we can do so usefully, and if you need further information you need not hesitate to write to us again.

Angle and Ventilation of Vinery (A Nine-years Subscriber).—The angle of the house, 45°, is quite suitable for Vines, but the ventilation at the top of the house is insufficient. This may be remedied by making every alternate light movable. As the roof is heavy the Vines must be planted thickly, those of the Gros Colman being fully 4 feet apart, and the others not less than 3 feet 6 inches. The house would be more suitable for Grape culture if every alternate sashbar were removed and the roof glazed with larger squares of glass, yet you may probably succeed without this alteration if the laterals are trained very thinly so that one leaf does not overlap another. If you make a good border and plant inside the house, allowing the roots access to a good outside border also, you ought to succeed in your object.

Vines in Ground Vinery (F. C.).—The removal of the vinery to a position where it will have more sun will undoubtedly be advantageous. The summer of 1879 was very dull and wet, consequently the wood of many Vines, also of fruit trees, was not matured. Your object must be to so place the vinery, and train and prune the Vines that every leaf can have full exposure to the sun. For this purpose many of the young shoots must be rubbed off in the spring, leaving the laterals that remain 18 inches apart; these, too, must be stopped a leaf or two beyond each bunch, or where there are no bunches at about six leaves from the base; all aftergrowths, sub-laterals, to be pinched out immediately they are formed at one leaf and before a second leaf is produced. By adopting this practice you will have good foliage, no useless growth, and matured wood of a fruit-bearing character. If the foliage is still on the Vines you may remove them now, doing the work carefully, not permitting the roots to become dry; replant in fresh soil, covering the surface 5 or 6 inches deep with half-decayed manure, and fresh root-action may commence at once. If the Vines are divested of their foliage prune them now, and remove them in spring when the buds commence swelling. Burnt soil and wood ashes are excellent for mixing with the soil in which the Vines are planted. Your Vines may produce a few bunches next year if the wood is ripe now, but they must be cropped lightly until they are established in the new position. We suspect your Vines have been much

too crowded with lateral growths, and in that condition Vines never produce good crops of fruit.

Forcing Asparagus (A Beginner).—When the roots are taken to a hotbed the bottom heat should never be above from 75° to 80°; if there is the least danger of the heat being more the roots should merely be left on the surface, and be slightly covered after watering, and then 2 or 3 inches more covering should be put on as the heat declines. The details of these matters are of primary importance to the inexperienced. For an early Asparagus bed we seldom use a hotbed all of fresh materials, but select an old hotbed which has been used for Cucumbers or Melons. The soil is taken off, also the most decayed part of the dung; that which is not quite rotten is stirred, mixed with hot tree leaves or other fermenting material, and 2 inches or so of the dung placed on the surface. On this are packed the numerous spreading roots, taking care not to let them get dry, putting in the first row as close as it is possible to do without the buds touching. A little leaf soil and sandy loam is scattered on the long roots, then the next row of roots is placed over them with the buds on a level with the first row. In this way a large number of roots can be packed in the space of a single light of 6 feet by 4. When all the roots are packed in, a sprinkling of light soil is thrown over them, and water is given at a temperature of about 65°, so that the fibres of the long roots may have no check. When sure that there is the proper heat, 50° to 60°, add a couple inches or so of covering, for, where green shoots are preferred, covering for blanching is quite unnecessary.

Names of Fruits.—We have received several parcels of fruit which will have attention next week.

Names of Plants (G. B.).—Both specimens were very much withered, especially the one with red flowers, which, however, is probably *Clerodendron fallax*; the other is *Antennaria tomentosa*. The *Antennaria* may be propagated by division of the plants. (W. G.).—1, *Maranta zebra*; 2, *Begonia Marshalli*; 3, *Adiantum assimile*; 4, *Gymnogramma peruviana*; 5, Insufficient for identification owing to the absence of fructification; 6, *Pteris longifolia*. (W. A. C.).—1, *Retinospora pisifera*; 2, Golden Milkmaid Holly, ordinary kind; 3, *Ilex seotica*; 4, *Juniperus drupacea*; 5, Golden Milkmaid Holly, best variety; 6, *Thuja borealis argentea variegata*; 7, *Chamaecyparis sphaeroidea variegata*; 8, *Cupressus Lawsoniana lutea*; 9, *Thuja dolabrata*; 10, *Spiraea Thunbergii*. (L. T. Last).—We received some sprays of *Selaginella*s, but they were so small and withered as to be quite unrecognisable. If you will send large and fresh specimens they shall be named if possible.

POULTRY, PIGEON, AND BEE CHRONICLE.

BREEDS OF CATTLE ADAPTED FOR DAIRY FARMING.

(Continued from page 449.)

As the late Dairy Show, held at the Agricultural Hall in London, suggested this subject we shall continue to take for consideration the breeds as they stand on the catalogue of the Association. Having previously made remarks upon the Jersey cattle we had intended now to examine the comparative richness of milk of the various breeds, but the returns relating the analyses by Dr. Voelcker are not to hand; we must therefore fall back upon our experience of more than fifty years.

Although the Jersey and Alderney cattle yield milk of fine quality for butter-making, yet we have always found the Guernsey breed excel them in the richness of their milk and deep colour of the cream. We have always been accustomed to purchase our Channel Island cattle of the importer immediately on landing in this country; we are thus enabled to speak of either breed as pure-bred stock. We can therefore certify that no breed will yield such rich milk as the Guernsey cow—in fact, we only recommend them as dairy cattle in connection with other cattle in order that the butter may be improved in quality and colour by the mixture of the milk in such proportions as will yield butter of fine cow-slip colour. In attempting to use the Guernsey breed alone for a butter-making dairy there is a great difficulty in summer time in making up the butter into pats or printed articles for sale, as it is sometimes found to run almost like oil, and nearly as deep in colour as beeswax. As this was how we found matters we were obliged to give up an entire Guernsey herd for butter-making, and keep them in part only with ordinary milking Shorthorns. The Guernsey cattle of the pure type are distinguished by their being much larger and heavier than the Jersey, and their capacity for yielding rich milk is easily discovered by ascertaining the colour of the skin inside the ear and on the tail of the animals, which is

of a deep yellow colour, much more so than the Jerseys, although the same in degree is a sign of quality of milk in those also. Before quitting the Guernsey stock we must observe that although the milk is so much richer than the Jerseys, as a rule they do not yield so much milk, especially when we consider that they are larger animals. They are, however, more hardy, and of considerable value when being fed for beef, as they always carry more flesh whilst in milk than the Jerseys.

We must now refer to the Ayrshire cattle as being good milkers, but yielding only a low quality, more like the Shorthorns. On referring to the origin of this breed we find it related that Quale, who wrote the "Agricultural Survey of Jersey" many years ago, states "that the Ayrshire was originally a cross between the Shorthorned breed and the Alderney." Our opinion is that they are more likely to have originated in a cross of the old Normandy cattle and the Dutch or Holstein breed, for we should look at the head and horn, and also the deep and even body on the under line, and the shape of the udder placed, as it usually is, very forward. As these points are not peculiar to the Jersey breed we are induced to give our opinion as above stated. However, be the origin what it may, these cows are excellent milkers, and will live on the highland pastures with the mountain sheep, and being enabled to bear the climate of the northern counties and Scotland this at once to our mind stamps them as being of other origin rather than either a Shorthorn or Jersey cross.

The Dutch or Holstein cattle must now be noticed as being very large cows and useful dairy cattle. At the Dairy Show there were eighteen entries, and we considered it the best collection of these animals ever exhibited in England. This stock has for many years been appreciated by the dairymen and cow-keepers in London and other towns as useful dairy cattle, and usually purchased at a moderate price, some of which are well calculated to feed for beef also, although they are generally light of flesh, being also thin and of a wedge-like shape in the fore quarters, which circumstance marks them in our estimation as especially adapted for dairy purposes. Whether we take the best milkers in Shorthorns, Ayrshires, Jerseys, or Dutch cattle, this lightness of the fore quarters, and especially of the narrow shape immediately behind the shoulder top, is as a rule the chief characteristic of great milking capacity: hence the difficulty found by the most eminent and practical breeders in maintaining a herd where aptitude to fatten with correctness of form and outline shall be combined with first-class milking powers. If we remember rightly, at last year's Dairy Show the prize for the largest quantity of milk at two milkings was awarded to a Dutch cow, but her milk when tested by Dr. Voelcker gave only 2½ per cent. of fat and a total of only 8½ per cent. of solids, a quality so low that it is actually below the standard as required for pure and unadulterated milk. There can, however, be no doubt the Dutch cows are so far in favour with cow-keepers as to find a ready sale in this country, if only the Dutch authorities will adopt stringent rules and sanitary regulations similar to those adopted in England against pleuro-pneumonia and foot-and-mouth disease. At present we find Dutch cattle are credited with the spread of both these disorders by their importation of cows into the Deptford market. Now in order that farmers may not be deceived in purchasing Dutch or Holstein cattle, it must be stated that they are nearly all of a black and white or tawny and white colour.

The Kerry cattle at the Exhibition were not numerous, but the first-prize winner was very well bred and showed a capital udder. These animals are small but well made, and are usually of a black or dark brown colour; they are also credited with giving a fair quantity of rich milk, even when they are fed upon cold strong land pastures, and have the character, too, of being hardy and healthy whilst feeding on short poor food. Considering they are

very small animals, they fatten very quickly when out of milk, and their beef is much esteemed by the butchers because it is of good quality and yielding small joints similar to the Scotch and Welsh animals, which sell at the highest quotations for beef. The heifer classes at the Dairy Show were not considered satisfactory, nor do we believe they are ever likely to be, for the reason that their milking powers are not fully developed, and we think that the Association may extend their prizes for cows and pairs of cows in some other direction, and especially in the encouragement of cross-breeding stock. Although the cross-bred animals exhibited at the late Show were not well defined by the appearance of the cows to enable farmers to say what the crosses were, yet, we think, on a future occasion with special encouragement and a statement of the breed of both sire and dam of each animal exhibited, it would be shown that cross-breeding dairy farmers have yet a valuable lesson to learn, which we shall endeavour to show in future observations.

We have turned our attention to cows only, but must not forget the bulls, because it is a moot question which has the greatest influence in cattle-breeding, the cow or the bull. It is a most important matter that the bulls should not only come of a milking family, but also that they show what is required in their make, shape, and outline; for if we select a bull for his correct breeding within the lines of pedigree, it is impossible to say that it will be the parent of the most valuable milking stock; we even go so far as to say that it is more likely to be the reverse. The same observations that we have made with regard to the best shape as a rule for the best milking cows, will to a great extent hold good in well-formed bulls, as required for begetting dairy stock. The early Shorthorns, at least when we first knew them, were frequently considered too light in the forequarter, and particularly behind the shoulder top, and at the cattle shows generally these had no chance of winning a prize, because this peculiar form was considered a defect. It is a defect we admit, if we are breeding cattle principally for the shambles, but not if breeding stock for dairy purposes; and we can only hope that judges, if they agree with us, will possess courage enough to award the prizes accordingly.

(To be continued.)

WORK ON THE HOME FARM.

Horse Labour.—The Wheat seedtime is now drawing to a close. Only a portion of the Turnip land where the crop is being fed off by sheep remains to be sown, and since the commencement of the present month there has been no hindrance to the horse labour employed in working the land and drilling Wheat; in fact, the period is not only right for seeding upon all good and dry land in good condition, but the state of the land has been all that could be desired. Although heavy rains have prevailed in most parts of the kingdom during a great part of the month of October, and the low lands were much flooded, yet dry soils were benefited by it, because the subsoil was comparatively very dry, and any excess of moisture has therefore been quickly absorbed. The strong lands have been too wet throughout the month of October, but even these since the 1st of November have been sown with Wheat in capital condition, especially where the home farmer has shown patience by waiting for the opportunity, although it came rather later than usual. We must now refer to the policy of sowing a full lain of Wheat, for during several years past a diminished acreage has been sown. We could not, however, recommend the home farmer at present to sow a short lain of Wheat, for the general opinion prevails that we have perhaps for several years touched the lowest point for our Wheat produce as regards price per quarter. This depends upon many circumstances, and cannot be acted on with safety. Our idea is that Wheat under any circumstances upon all dry or good mixed soils should be considered the rent-paying crop, and is likely so to continue. If the weather should prove dry and favourable, as at the time we are writing, much of the land under autumn fallow, whereon the couch grass has been harrowed and brought to the surface, may be cleared of the couch and rubbish before the land is deeply ploughed to lie the winter. Some farmers do not hesitate to plough the couch in again, even after lifting it out of the land by costly labour; but this is altogether wrong, because we have had no weather this autumn to kill the white-rooted couch: indeed, summer weather will not always destroy its peculiar vitality. We therefore never advise its being ploughed down at any time. The sowing of green crops has been finished a long time, if not in proper season, and we find both Rye and winter Tares are doing well; but with regard to Trifolium the plants have been destroyed by the slugs in numerous instances. We remember, however, a similar season when the slugs destroyed our first sowing in September after sowing 20 lbs. per acre. We then in October sowed 25 lbs. per acre on the same land. This was also destroyed, but on the 13th of November we sowed 30 lbs. per acre, and although a hard frost occurred soon after the seedlings appeared it stopped the slugs without injuring the Trifolium, of which we had a valuable crop in the summer, although a little later than usual. We consider this crop of so much importance that we do not hesitate to sow late and use

large quantities of seed rather than be without the crop in early summer.

Hand Labour.—Mangolds and Potatoes should be finished heaping and storing without further delay. Some farmers leave spaces on the top of the heap to allow heat to escape, but this also allows the rain to enter. We prefer 2-inch drain tiles set on end upon the top of the heap at certain distances: this permits any results of fermentation to escape without admitting rain. The dairy cows now require our especial attention, for their well-doing and giving a good supply of milk depends upon the food they receive, and in case of a dairy for furnishing milk during the winter and spring months is kept, fresh purchases of cows that have newly calved must be made. It is better to foresee this matter, and insure the calving all the year round of the stock on the farm in order to insure a supply of milk during the whole year. The sheep feeding off roots upon the land have done well up to this time upon all dry land, but when roots are grown upon heavy flat land they should be either carted away for cattle, or otherwise pitted on the land to be fed by sheep on the land during March or April next, when the land will bear the tread of the animals without injury in ordinary seasons. The hay is very inferior this year, being damaged by rain as much or more than in any season we ever remember. It may be spiced at the time of cutting into chaff if the spice was not applied at the time of stacking, for when hay is taken up after much rain it still contains nutriment although it does not attract the stock. We know of no better or cheaper spice than that sold by Bowick & Co. of Bedford. As the pastures are short of grass, all young stock should receive Cabbages strewn on the pastures, also those dairy cows which go out to feed. The down ewes in lamb should now have grass as long as possible, old lea being best; they may, however, have some Cabbages upon dry pasture at night. No low-lying meadows should be fed off by sheep at this time of year. We find that there is a plan started for the treatment of pastures, that where sheep are found to suffer from coathe or rot—namely, to apply a moderate dressing of common or manure salt, or fishery salt to the pastures now, and another dressing again in March. This is said to kill the fluke egg or entozoa, but it should be done every season wet or dry; the fluke will then be destroyed in embryo, and the pasture will be benefited, especially if fishery salt be used. The horned Somerset ewes are now lamming fast, and this is a season especially favourable for them, for the Italian Rye grass in the Wheat stubbles has furnished abundance of food, and will continue to do so for another month if the season proves mild. The ewes and lambs, however, ought not to render the young Clovers too bare, nor yet lie thereon at night time, for it not only injures the Clover plant when we have night frost, but Clover layer proves bad for young lambs, the Wheat stubbles being warmest for night quarters, as we frequently find the lambs suffer from a kind of rheumatism and swollen joints. From this they never recover, but should be killed and replaced by others.

CRYSTAL PALACE POULTRY SHOW.

ONCE more the poultry fanciers' great "Derby" has come round, and the Crystal Palace is lined from end to end with Mr. Billett's pens. The public were admitted on Monday, and the Show remains open till five o'clock this evening. It is the twelfth of the revived series of annual shows; large to begin with, year by year it advanced till it attained its present immense proportions. It seems as if this were its utmost limit; and though the quality of the exhibits may improve, their numbers are stationary or vary little from year to year. The result is that each class comes as nearly as possible into the same position it has before held, and we can scarcely realise that we are looking at a set of birds, one-half of which have been hatched since we last saw the Palace Show. For one year the Pigeons were dispossessed from their central transept, but there they are again in all their beauty, and certainly there is no place like it for seeing them. But we must not generalise about the Palace; everyone knows it, and every fancier knows the charming view it gives of feathered stock. Those, however, who are not fortunate enough to get to it will want to know some particulars of the year's results, and how they and their friends have fared in the poultry wheel of fortune.

Dorkings of course come first. We have seen the Darks more numerous, but their average excellence is high. The first adult cock is a square dark-coloured bird in good condition; second a fair but not striking bird; third a nice short-legged bird and good in colour. The cup goes to the first hen, a famous old winner which has stood before in the same position; her day is somewhat past, still she is in good plumage again, though somewhat loose in crop. Second is a deep-bodied bird, short in leg and in good condition. Third is very large and fine, a good Dorking in shape. Fourth rather small. Cockerels are a fine class of sixty-seven. The cup bird is broad, deep, and massive, very dark with bronze on the wing; second has a nice comb and short legs, but white earlobes; we liked the third, a very large bird; fourth also large, but a very suspicious appearance about the back of his comb; fifth a pretty but very small bird.

Many others beyond the prize birds are worthy of their notices. 35 (Lord Winterton) is large; 45 (Beachey), good but white in ears; 48 (Pilkington), deep in body; 57 (Lingwood), gigantic, with five toes to match his size. Pullets numbered twenty-five. The cup went to a rich-coloured bird good all round; second large with very white feet and pretty comb, but a little light in colour; third we thought a mistake, she has very sooty feet and is not striking in any point; fourth a good square pullet, which we preferred; fifth a fair bird with big and ugly spurs; 73 (Mrs. Hind) about the largest bird in the class, with good white feet, a little rusty in colour or she must have won; 81 (Warren) has nice white feet; 84 (Cresswell) very fine but a little light in colour; 92 (Taylor) a large handsome pullet. In Silver-Greys—Whites—the Judge has gone in much for colour, and less than usual for size and form. The cup Silver-Grey cock is a really good and silvery bird; second good in colour and fair in other points; third small and poor in comb, but silvery also. The first hen is very fair, square, and in good condition; second a big bird with an ugly comb; third has been a fine hen, but her day is over. The cup cockerel is not large, but well shaped and good in every point, and well deserves his place; second is as silvery, but ticked in breast; third is sprightly, but poor and small. Several immense birds are highly commended only, doubtless because they fail in purity of hackle and back colouring. The first pullet is very large and pretty; second and third both good and well chosen. Cuckoos are looking up, and a great improvement on past years. The first pair are young, of a good dark colour and rose-combed; second pale in colour, and we do not like the cock's wry rose comb; third are single-combed, very well marked, as are generally single-combed Cuckoos, but the cock is too white in tail. The White Dorking judging is somewhat of a mystery; we long thought that the cup card had got on to the wrong pen, but are informed that this is not so. The cup cockerel is very white, very small and pretty chicken; second a noble old bird; third a fair cockerel. The first hen is very white, and that is all we can say; the second a much better bird. The first Darks in the £5 selling class are a magnificent pair.

Cochins.—Buff cocks a fair class of eleven. The winner clearly ahead in size but rather coarse in comb; his hocks nicely turned, and ample foot feather except on the middle toe. His colour rather too much in the tricolor type for our taste; however, he was well ahead of the rest of the class. Second a nice even-coloured one, but smaller and rather flat in back. Third heavily hocked and wings slipped, good in shape and carriage, but showing too much streak in saddle hackles. 200 (Hind), highly commended, a pretty lemon, small in size and heavily hocked, but to our mind better than third. Buff hens.—A good class of eighteen. First and winner of the cup for cock or hen a beautiful light shade of buff, round as a ball and well fluffed out. If she have a fault it is in carrying her tail rather too high. Second rather darker in colour and a trifle coarse in head, also slightly too high in tail. Third large in size, but with one defective eye, and rather straight in back. All three winners were hocked. 220 (Brown), highly commended, good in shape and carriage of tail. 224 (Bloodworth) very highly commended, a grand cushion but not quite clear in colour. Buff cockerels.—A good class of twenty-eight. The winner, which also takes the Buff chicken cup, is an evenly-coloured lemon with a rather mis-shapen comb and rather heavy hocks; he wants solidity a little, but is otherwise of good shape. Second an even-coloured light Buff with nicely rounded hocks, pressing very closely on the winner. Third a lemon again, but not quite even in colour and wings rather loose, comb ugly at back. Fourth a fair Buff. Most of the noticed birds were good. 245 (Proctor) very highly commended, struck us as being a particularly good one but for the large size and defective carriage of his wings. Buff pullets numbered thirty-nine, and was by far the best class of Buffs. First was a beauty in all points except comb, which was rather too large and weak, and a slightly twisted hackle. We should, we think, have gone here for the cup. Second hocked, and not quite so even in colour, which was a dark shade of buff. Third a light buff, even in colour but hocked again, and if anything rather too close in plumage and narrow in saddle. Fourth rather darker in colour, good in shape and feather. 268 (Davidson) very highly commended, a very shapely pullet but a little broken in colour. 279 (Causer) good in shape and colour but small, worth a card. 291 (Long) very highly commended, very shapely also. Partridge cocks numbered twelve, and no less than ten of these were deservedly noticed. As a class they were much superior to the old Buffs. First and cup for Partridges very brilliant in colour and in the pink of condition, but failing in saddle. Second more massive, and will surpass the winner later on unless the white in his tail develops too much. Third very massive, but only half out of his moult. Partridge hens.—Another very good class, numbering fifteen. Almost every one of the ten noticed birds was really first-rate. The Judge seemed to us, however, to go in rather too much for the old type to the exclusion of the more clearly pencilled modern style. 308 (R. J. Wood) highly commended, we thought the best bird in the class, as she had a wonderful breast, and was of fine size and shape; she had, however, a severe cold in one eye, which perhaps threw her out. Partridge cockerels (twenty-one) were not as a class up to the quality of the old birds; many were undersized and far too coarse in comb. The winner was good in shape and colour, but only moderate in size and coarse in comb. Second and third moderate in quality. 333 (Morris), very highly commended, struck us as the best Cochin in the class, but his very dusty neck hackle doubtless threw

him out. Partridge pullets (twenty-nine) were as a class of good average quality, but contained nothing very startling. Here again we could not quite agree with the Judge. Second would have been our choice for winner; her only faults in our eyes were a few white feathers in feet and hocks. First was not so distinct in markings and inferior in shape to second. Third might also with advantage have made way for 362 (R. J. Wood) v.h.c. good in size, shape, and marking. White cocks numbered only five (with Mr. Darby's pen empty), and were not good at that. First good in colour and shape, but rather too much tail; second and third either dirty or yellow in hackle. White hens (nine). First and cup for Whites a really grand hen, deservedly placed at the top; second also a good one, but not equal to the winner—indeed, we should have placed the third above her. 380 (Darby) was second here, and first at Birmingham last year as a pullet. She is not through moult and has to grow, but will make her mark yet as a hen. White cockerels were only eight in number. Mr. Darby's Dairy Show bird here came to the front again. He is wonderfully free from yellow, and is indeed a good bird all round. Second good in colour but small; third larger but rather yellow. White pullets (ten) were again headed by the Dairy winner, a wonderfully perfect pullet. She walked away from second and third, though neither of these were inferior. Black or Langshan cocks were five in number, four being Cochins and one a Langshan. We wonder that any Langshan breeder entered in such classes. All the prizes went to Cochins, Mr. Cowell being highly commended in each class with Langshans. First very large and good in all points except comb, which was not quite straight. Second, also, only failed in comb, which was too large. Third smaller, but very glossy and fine in head. Hens were eleven in number. First was a large finely shaped hen with a good gloss. Second not nearly so large, but attractive in style. Third was quite out of sorts, and should have given way to Mr. Cowell's Langshan hen. Cockerels (eleven). The winner took his place and the cup by size and condition; his shape was hardly correct, as he had a round hack and carried himself too erect for a Cochin. Second and third were of a more correct Cochin type, but much smaller. 423 (Lady Gwydyr) highly commended, the pick of the class but for his coarse comb and wattles. Pullets (fourteen). Not much to choose between the three winners, first being best in saddle but rather short of foot feather for her hocks. Second a little coarse in comb and dull in colour. Third in brilliant condition and good in all points except cushion, which is hardly high enough. The five-guinea Cochin selling class contained some good birds at the money, but nothing startling.

Brahmas.—The Dark Brahmas this year were judged by Mr. Raines, the first time, we think, that he has officiated at the Palace; and though there were of course the usual per-centage of grumblers, we think, as a whole, the judging was satisfactory, the best birds in the classes generally taking the prizes, though the order in which they were placed might in some cases have been altered with advantage. In old cocks size seems to have been considered a good deal, and the cup went to a very large bird, but his want of shape made him look ungainly. Second was another large bird, and we rather preferred the same exhibitor's highly commended (482), which was better in most points except size. Third was the best-shaped bird of the four, and certainly deserved his position. Fourth another large awkward-looking bird. The class as a whole was good, though inferior to what we have seen in past years; most had bad coarse heads. 467 (Comyns), v.h.c. was one of the few that had good combs. 476 might have been noticed, though not so good as Mr. Lingwood generally shows. The first old Dark Brahma hen was a magnificent bird; with the exception of a slightly brownish cast on the wings, she is nearly perfect, and the condition she was shown in was a great credit to her owner; she should certainly have had the cup. Second was a grand hen, but rather too Cochiny in shape. Third rather too high on leg, and fails rather in marking towards the tail. Fourth a well-feathered bird, but otherwise there was not much to choose between her and her neighbour. 487 (Taylor) c. Cockerels were a grand class of nearly fifty entries. Mr. Lingwood is to be congratulated on a success as unparalleled as it is deserved, for four better birds were never sent out from one yard; indeed, we might almost say from any yard. They were all grand in shape and width, and good in comb—three points in which we have noticed a general falling-off this season, a slight difference in colour and size making the difference between them. Fifth a pretty bird, lacking size. Sixth wanting in leg feathers, and altogether hardly so good as the same exhibitor's 533, commended. Seventh a large bird, also rather short of feather. 540, very highly commended (Kendrick), and 559, un-noticed (Gwydyr), both good birds above the average. Dark Brahma pullets numbered about forty. First a well-known bird, looking rather overdone and out of condition, but deserving her position. Second a good pullet, nice shape and leg feathers, but rather hazy in marking on both wings and cushion. Third large but rather stilty, and disfigured by inside leg feathers. Fourth a fine large pullet, but also rather too high on the leg. Fifth a good Dark with heavy marking. Sixth not equal to what Mr. Percival generally shows, as she was rather mossy in her marking, though a pretty pullet otherwise. The class was altogether a good one, and we should think most difficult to judge, as, though there was nothing of a very high character except the winners, there were a large number of birds above the average quality of show specimens. Old Light Brahma cocks were a small but good class. The judging was hardly satisfactory, many

complaints being made, and we think justly. The cup and second were very large birds, very narrow with enormous hocks; the second had also a dark smutty hackle; third was a good all-round bird and deserved his position; the fourth we preferred to any, and should have placed him first with 630 (Ive), unnoticed, second, and put 629 highly commended (While) fourth. Old hens were good, and most of them well through the moult. The cup went to a beautifully coloured bird of Mr. Lingwood; she only wants a little more leg feather to make her almost perfect. Second went to a fine large hen rather too Cochiny for our taste; third and fourth were both rather sandy in colour, and we preferred Mr. Mitchell's, 646, highly commended, to either. The cup cockerel we did not much admire, as he was yellow and rather hollow-chested. The second was rather better, but we would rather have had the sixth-prize bird than either; he was grand in colour, shape, and leg feather, but unfortunately had slipped his wing, had it been all right we think he would undoubtedly have won the cup. Third we thought should have won, being the best all-round, though several had better individual points. Fourth showed rather white in tail, but otherwise was a good bird, and might well have been higher. Fifth also rather too white a tail, and failed a little in depth of chest. 675 (Wood), highly commended, was a good bird, and would have stood a better chance if he had been on the lower row; in fact, some of the birds being on one level and some on another made a material difference in the chances of many. Pullets were the best class we have seen for some time. The cup went to a splendid bird, almost her only fault was rather a lack of foot feather. Second and third were both rather creamy, but otherwise were both good pullets, though we rather preferred Mr. Lingwood's fifth-prize bird, which was a beautifully clear colour, and very good in general Brahma characteristics. Fourth was a grand pullet, and had she been properly washed would have very likely taken a higher position. Sixth was a fine large bird, but rather too creamy in colour—a very prevailing fault. Amongst the unnoticed birds we thought Mr. G. H. Wood (706) was the best.

(To be continued, with the prize list next week.)

VARIETIES.

BROXBURN ORNITHOLOGICAL SOCIETY.—The first annual Exhibition and Competition of Poultry, Pigeons, and Canaries (open to the United Kingdom), will be held in the Town Hall, Broxburn, on Saturday the 25th December, 1880. The assistance of fanciers is requested to make the Show a success, and enable the Committee to increase their prize list on future occasions.

— **IRISH BUTTER.**—The butters of Ireland, as seen at the leading shows, will not suffer by comparison, all things considered, with those of England, or of the countries of northern Europe. That there is a larger proportion of inferior butter made in Ireland than in any other country which reckons to be a dairying country at all is probably true, but it is equally true that some of the best butter in the world is made there. It is merely a question of care and cleanliness. At any rate a collection of Irish butters shows more body, substance, and general quality than we have found to be the case in other countries. At the same time we must admit that they are less skilfully made and less neatly finished off and presented than, for instance, the butters of Denmark or of Finland. Possessing an inherent superior quality they lose the advantage of not being so skilfully made. With one of the finest climates on earth for dairying purposes; with a soil and herbage which are not easily equalled; with a breed of cows excellent in many respects, and still improving; and with milk pre-eminently suited to butter-making—more so, perhaps, than the milk of any other country in the world—the Irish people are provided with the first requisites for becoming the leading butter-producing nation in Europe. But to attain this position requires, in our opinion, the untiring industry, the scrupulous cleanliness, the intelligent thought, and the pride in work which are conspicuous among the Dutch and the Danes.—(From "*Dairy Farming*," by Professor Sheldon, for November.)

— **THE AMERICAN DAIRY INDUSTRY.**—At the late convention of the American Butter and Cheese Association the President of the North-western Dairyman's Association, Hon. G. P. Lord of Elgin, Ill., read a paper, in which he estimated the number of milch cows in the United States at over 13,000,000, requiring the annual product of 52,000,000 acres of land for feed, giving employment to 650,000 men, and requiring the labour of 866,600 horses. Estimating the cows at 30 dollars each, the horses 80 dollars, and the land at 30 dollars per acre, together with 200,000,000 dollars for agricultural and dairy implements, and the total amount invested in the industry is

2,219,328,000 dollars. This is considerably more than the amount invested in banking and the commercial and manufacturing interests of the country, which is 1,800,964,586 dols. Accepting 12 cents per gallon as a basis for computing the value of the milk product, and 446 gallons as the average per annum (this being the average yield in sixteen States in 1860), the 13,000,000 cows produce annually 5,793,000,000 gallons of milk, worth 695,760,000 dollars. Analysis shows that 3½ lbs. of milk contain the same kind and amount of nutrition as 1 lb. of boneless beef. The total weight of product is 50,732,600,000 lbs., equal to 14,495,000,000 lbs. of boneless beef. About 50 per cent. of a fat steer is boneless meat, so that it will require 20,650,000 steers of 1400 lbs. weight to produce the same amount of nutrition as the annual milk product. Such fat steers would sell at 4.50 dollars per cwt., or 63 dollars each—a total of 1,300,950,000 dollars; deducting from this amount hide and tallow, 260,190,000 dollars, leaves the meat value 1,040,760,000 dollars. This gives the food value of the milk product in the United States annually. Willard, in his "*Practical Dairy Husbandry*," says that "milk at 24 cents per gallon is equivalent in value to boneless beef at 9 cents per pound." It is false economy, therefore, that substitutes meat for milk as an article of food.

— **THE WHEAT SUPPLY AND PRICES.**—A daily contemporary concludes an exhaustive article on this subject as follows:—"We have received up to November 6th from all foreign and colonial sources of supply 15,937,026 cwt. of Wheat and flour against 18,082,870 cwt. in the same period last year, or a falling-off of 11½ per cent. We are importing at the rate of about one-ninth less than the 16½ million quarters imported in the twelve months ended in August, and if 14½ or 15 million quarters will be sufficient to supplement our weak home crop of probably 9,000,000 quarters until next harvest, imports coming in at present speed will be all we require. The backwardness which has ruled in the movement of American grain may continue, and the failure of great shipments from Russia and Germany may not be made up from other sources beyond the sea; but we really want no more for the year than is pointed to by the arrivals during the last two and a half months, it being admitted on all hands that our home crop of Wheat—deficient as it is compared with a fair average—greatly surpasses the starvation product of 1879, when 16½ million quarters of imports were found ample for our consumption. Agriculturists may be gratified with the brisker markets they are hoping for, but there seems little probability of the rise being anything more than a moderate advance, and that, perhaps, not long continued."

— **THE MILK SUPPLY FOR LONDON.**—The Report of the Local Government Board for 1879-80 states that "Londoners are paying between £70,000 and £80,000 a year for water sold under the name of milk," and the statement is supported by figures which leave the impression of its truth. No return of the milk supply has ever been made, and the actual quantity consumed is estimated from data which are not very clear or satisfactory. It is found that the railways bring into London nearly 20,000,000 gallons a year. The Board reckons that some 3,000,000 gallons are probably produced within the metropolitan area; and the 23,000,000 gallons thus supposed to constitute the whole supply allow to each person one pint of milk a week. This estimate of individual consumption seems to us to be far too low, unless the working classes in London are very sparing in their use of this article of food. It represents, however, at 5d. a quart an outlay of about £2,000,000 sterling.

QUEEN ENCASEMENT, OR REGICIDAL KNOTS.

THIS question has lately been discussed in a thoughtful letter by Mr. Cheshire. At one time I was inclined to believe that the clusters of bees surrounding queens, so often seen in uniting swarms, were formed to protect them amongst strangers or from those bent on their destruction. In every case of this kind that has come under my notice during the last ten years, the knots or clusters were formed with murderous intent, and now I am convinced that all the small hard clusters of bees encasing queens are regicidal in their aims and never protective of life. Last summer I noticed two interesting cases. One was formed by the bees of

a first swarm on being hived. The queen, healthy and only twelve months old, left the stock hive with the swarm, but being without a wing she could not fly or follow the swarm. The swarm was hived and the queen given to it. In about two hours after I saw that something was wrong, and on lifting the swarm hive I saw a regicidal knot on the side of the hive halfway between swarm and board. This knot was rolled on to the board and the queen liberated. A second time she was encased and liberated, and next morning she was found dead under the flight board. Why did the bees kill her? I could not tell. Believing that the swarm was queenless, I thought the bees would return to the old hive, but they remained where they were and commenced to work and build combs as if nothing had happened. I gave the swarm a piece of comb containing eggs, expecting that royal cells would be formed and tenanted, but none were built. I took an old queen from a weak stock and gave it to the swarm. She, too, was killed and cast out. Meanwhile the swarm prospered and had cakes of brood sealed in less than a fortnight from the time of swarming. That they had a queen or obtained one in the act of swarming there can be no doubt, but where she came from was a mystery. There was no other hive in the garden ready for swarming. Had I not been on the spot and witnessed the whole affair I should have concluded that two swarms came off at the same time, but after much consideration I found no evidence to support such conjectures. The swarm is now a strong stock.

Another instance of queen encasement is more easily understood. In August last a gentleman in this neighbourhood begged me to drive the bees from one of his honey hives and take them for the trouble. After almost all the bees were driven into an empty hive an attempt was made to kill and clean out the stragglers by sulphur. A small bit of paper sprinkled with sulphur was ignited and the hive placed over it. On lifting the hive it was found that the sulphured paper had been extinguished before the bees were destroyed. On shaking them out it was seen that though not killed they were much injured and unable to fly, and that the queen, a beautiful half-bred Ligurian, was amongst them. She was picked up and given to the driven bees. They did not know her and would not have her. She was speedily encased by a cluster of bees bent on her destruction. They were not disturbed for an hour or more till the smell of sulphur had nearly passed from her body. She was then liberated and seen to run into the body of the swarm, and is now the queen of a healthy stock.

The conduct of the bees in this case leads me to notice a thoughtful remark in Mr. Cheshire's letter. He says, "Since bees have the power of recognising every member of their own big household and distinguishing every stranger, it is quite likely that little matters which we cannot detect are to them as conspicuous and distinct as facial expression is to us." This is correctly stated. Bees have such powers, and in such cases that of smell seems to be the most powerful and useful. The sulphured queen appears to have been detected and rejected by smell, and that the sense of sight was not called into play at all; indeed, for indoor work the sense of sight is unnecessary. They possess compensatory powers. I think it will be very difficult to prove that bees know members of their own family by sight. If they do they have short memories, and soon forget them. If a swarm, natural or artificial, be taken from a stock hive the bees of the swarm would be recognised and received by the mother hive if they went back within one or two days, but if kept away for a week they would probably be killed at the door of the hive on returning. In uniting swarms the danger of fighting and destruction is at the time of uniting. If the two swarms remain for half an hour without fighting they become one family to all intents and purposes. Smell seems to be the only bond of union.—A. PETTIGREW.

HEATHER HONEY.

THE year 1880 will long be remembered by our highland bee-keepers as perhaps the most productive honey season ever known hitherto. I have just returned from a three-weeks tour, during which I have visited the leading bee-keepers along the lines of the Highland, Great North, and Deeside Railways, and the general testimony has been that never before did bees do so well on the Heather. Nor has success been confined to those who practise the modern methods of culture, the number of weighty brimstoned skeps being marvellous to see. While our lowland bee-keepers are lamenting over a poor yield, those in the highland districts can well afford to take heart, for not only has the yield been exceptionally large, but the sale of the honey has been such as to make it almost impossible for me to obtain a few supers of which I was in need. One bee-keeper of the modern school had not only sold all his own to the amount of about £40, but had to purchase

about as much again to fill orders, and this at a uniform price of 2s. 6d. per lb. The one condition for securing so satisfactory a price was that the genuine Heather honey should be stored in neat packages, sections of 1 or 1½ lb. being preferred. Everywhere I have found that a decided preference exists for Heather honey, and that double the price of Clover honey is readily obtained for it. The demand is also on the increase, partly because of its delicious quality, and partly because the taste for lowland honey has to a great extent become cloyed. The latter is often so polluted by so-called honeydew, and so nearly resembles the insipid American honey, that persons once accustomed to both almost invariably settle down on the Heather as the honey *par excellence*. Such being as I believe the case, a grand opportunity is offered of turning to account the thousands of square miles of blooming Heather with which our country abounds. How to do so to the fullest extent is the problem I would venture to lay before my fellow bee-keepers. The bee books and journals give us little if any assistance. They do acknowledge the desirability of "removing bees to the moors," but there they halt. They give no idea of the special treatment that stocks must receive before they can take full advantage of what in most seasons is really a harvest "out of season." As a rule they give directions only for obtaining the largest results from earlier harvests, and as a consequence those who follow their advice find themselves on the advent of the Heather season with stocks diminished in population, brood-raising almost suspended, and the brood combs glutted with honey. It will thus be evident that in such a common case only very moderate results can be obtained; and when it is noticed that the population of a hive working on Heather dwindles in an exceptionally rapid way, and that the instincts of the bee lead it so late in the season to store all it can in the brood nest to the exclusion of the queen from laying room, the need for some explicit and special rules for working the Heather harvest will be evident. In a future issue I hope to contribute my share to this end, but meanwhile I shall continue to notice such facts as I have observed, and from which our special rules of treatment may be deduced.

I have found that in purely highland districts late-swarming hives yield returns quite as good as those that swarm earlier. Their larger proportion of young bees is probably the reason. The region of Aboyne and Braemar, where swarms are as late as the 1st of August, yields enormous returns. In these districts the ordinary dome-shaped skep is the rule, and extension is liberally given as required by the addition of wooden ekes. These afford the necessary breeding space from time to time, and serve thus to maintain the population to the close of the season.

I have been much interested in finding that bees do work to a large extent on the two species of Heather (*Erica tetralix* and *E. cinerea*) that bloom in July, a month before the common Heather. My friend Mr. Paterson of Struan kindly invited me to partake of the contents of a 1-lb. section of the whitest comb I ever saw, and asked whether I could recognise the source from which it had been gathered. In spite of my conceit as a judge of honey I had to confess myself at fault. The delicious flavour was quite new to me in white honey. He then informed me it was gathered from the Bell Heather—the two varieties mentioned above—and that his bees had forsaken the Clover to work on it in July. A visit to the hill behind his house revealed such a profusion of these Heaths as I had never seen before, and I could not wonder again that his honey was in such demand. This discovery at once explained what I had often observed, that some districts yield Heather honey so much darker in colour than others, the darker grades having a decided bitterness and tendency to catch the throat quite different from this lighter-coloured quality.

There is evidently a difference between the honey yield of Heather on lowland moors and that on the hills. My own bees gathered but sparingly from the moor beside them, and that only until the later bloom on the hills appeared. They then almost entirely took the opposite direction for the hill. The nearest Heather in this direction is between three and four miles distant, and gamekeepers assure me that they saw my Ligurians in abundance at five miles off. Others have informed me of finding Heather honey in their hives this season for the first time, and in some cases the distance must have been even greater than mine by a mile or two. As it turned out I had three-fourths of my surplus pure Heather. The further we advance inland the more abundant seems the flow of nectar, and I could not help lamenting over the scores of miles of purple Heather where I was informed that no bees were kept at all. I have had the honour of introducing the matter in the far north to the notice of the flourishing Farmers' Society at Inverness. The proposals I made for their taking the lead in developing the industry of bee-keeping, the public lecture that followed, and the open air manipulation

of bees on the following day, seem to have aroused quite a large amount of interest, and promise to bear fruit in the near future.—**WILLIAM RAITT, Blairgowrie.**

PRODUCTS OF BAR-FRAME HIVES.

I HAVE read with much pleasure your correspondent, Mr. J. Thomson's, account of his honey harvest from a bar-frame hive, inasmuch as it gives interested, though yet unprejudiced, persons an opportunity of judging of the relative merits of the straw-skep *versus* the bar-frame system of management in a similar district as to honey gathering, and evidently also under equally proficient handling. It is the first answer to Mr. Pettigrew's challenge to "the bar-frame hive gentlemen" to "send their reports," and to my thinking is decidedly a point in favour of the latter. Mr. Thomson deduces weight of hives and floorboards, and his calculation is decidedly within the mark, as I have Pettigrew hives weighing 8 lbs., and not of the largest dimensions, yet he has deducted nothing for weight of bees, combs, pollen, &c., which he should no doubt also do to be correct. We all know pretty well what the Pettigrew hive is; but I daresay many of your readers, like myself, would be much obliged to Mr. Thomson if he would inform us the style of hive he manipulates. Is it the Stewarton or other frame hive? and if so, what are the dimensions of the frame he uses, and how many frames per hive? If other gentlemen giving us accounts of their results would kindly give us a few more details of this description, I think it would tend to the advancement of what we all have at heart—viz., successful apiculture. In your issue of the 4th inst. I note "B. & W." is of opinion that frames of 14 by 9 would be a good size, those he has in present use (he does not give their dimensions) being too small. Now I have frames of 13 by 9, and I believe they would be better were they from 10 to 12 inches deep, as I find this season the brood confined to too small a space near the bottom in consequence of there being so much room occupied by honey and pollen in the top part; and as the queen seems to prefer to centralise the brood nest as much as possible, I think we may adopt frames nearer the American pattern of 12 by 12 with advantage. Possibly some of your esteemed correspondents will kindly give us their ideas on this, as I think, rather important matter.—**M. H. MATTHEWS.**

ARTIFICIAL COMB FOUNDATIONS IN STRAW HIVES.

FREQUENTLY I have been asked how these foundations could be fixed and used in straw hives. My reply has been, that the bar-frame or moveable comb hive affords greater facilities for the use of comb foundations than straw hives, but that if the foundations be proved to be of substantial advantage in apiculture, a successful way of using them in straw hives will be invented and adopted. Some time ago it struck me that by using wooden crowns in straw hives, and cutting out narrow slits from 8 to 10 inches long, and at proper distances apart in them, the foundations could be easily dropped down through the slits, and securely fastened by drops of melted wax or wedges. This seems easy and simple enough. The cross-sticks, so necessary in large straw hives, should be fixed before the foundations are introduced, and fixed just low enough to admit the foundations without touching. The bees on commencing work would fasten them to the sticks, which would give strength and stability to the whole. Hives with large crown holes and wooden lids could be treated in the same way, the slits of course to be made through the lids. Wooden supers, too, could be filled or half filled with foundations dropped in through narrow slits in their crowns and fastened by drops of melted wax on the outside. Be it known that all this is suggestion, but suggestion so self-evident of a practical character that the merest novice in bee-keeping will lose sight and fear of the difficulties of introducing comb foundations in his hives and supers. As I am still of opinion that foundations will yet be found to be very useful and profitable in various departments of apiculture, I shall be pleased if all the schools give them a fair trial next season and record the results.—**A. P.**

OUR LETTER BOX.

Ducks (J. S. W.).—Your Ducks are evidently cross-bred, probably between Rouen and Black East Indian. This cross produces black birds with white on their breast; had the cross been with Pekin they would have been half white. The birds you have, though of no use as exhibition Ducks, should be excellent for the table. The Black East Indian is in our opinion the best domestic Duck for eating, though small.

Chickens not Thriving (P. S., Keighley).—Your birds appear to be affected with catarrh. Keep them in a warm dry place, and wash their nostril

with vinegar and water. A teaspoonful or two of castor oil, according to the age of the birds, may also be of benefit. They require, too, more generous food, such as oatmeal and bread mixed into the form of a dry paste with strong ale. For fattening feed them liberally with oatmeal or barley meal mixed with milk; a little of Spratt's food and kitchen scraps will also be of service, with whole sound grain at night.

Pullets Laying (D. A. T.).—Well-developed pullets now six months old ought to lay in January. We recommend stimulating food to hasten their laying, but should give it by adding to their ordinary meal a little pot liquor in which meat has been cooked, table scraps, stale bread with beer, all of which are natural and healthy helps.

Parrots Falling from their Perches (B. C. W.).—Your bird is suffering from vertigo and nervous weakness, which is the cause of its falling from the perch. Parrots are very liable to the said accident, which is encouraged and brought about through being kept in a somewhat confined and warm temperature. When the fits occur give it a few drops of brandy and water. Give it a tepid bath two or three times a week. After the bathing and during the time the feathers are wet, spurt from your mouth a teaspoonful of brandy over the Parrot, after which throw a cloth over the cage and place it within 2 or 3 feet of the fire. When partly dry remove the cloth and hang the bird up. Accompanied with sound food this will tend to strengthen the bird if it is not past recovery. If you give your Parrot much meat, partly discontinue it, for it produces laxity and weakness. Give bread soaked in milk, and a little ripe fruit occasionally.

Bees not Taking Syrup (J. J. Cresswell).—Your hive is doubtless a weak one, and the lateness of the season and coldness of the weather are against your efforts to make it stronger. Even strong hives are slow to take syrup in cold weather. Make your syrup sweet enough, and while it is warm sprinkle half a pint of it over the combs and bees of your hive, close the door to keep the bees in, then remove the hive to the side of the kitchen fire. As soon as the combs are dry give the bees another feed, and then another, till they have enough. The door of the hive of course should be closed while it is in the kitchen, and the examinations and sprinklings should be done in the garden where the bees stand.

REMARKS.

7th.—Overcast except for short time at noon, slight shower 9.30 P.M.
 8th.—Very fine with much bright sunshine.
 9th.—Fine bright morning; overcast afternoon; cold day. [and evening]
 10th.—Fine with bright sunshine in forenoon; slight fog latter part of afternoon
 11th.—Rain in morning; damp overcast day.
 12th.—Rain first part of morning, clearing off at noon, fine and mild rest of the day; lunar halo 9.15 P.M.
 13th.—Fair but damp, very windy.
 In spite of one cold day (the 9th) the weekly means of temperature are far above those of either of the three preceding weeks, and slightly above the average.—**G. J. SYMONS.**

THE VALUE AND IMPORTANCE OF SHELTER. A HINT FOR SHRUB PLANTERS.

TWO winters of extraordinary severity, with a cold and wet summer intervening, have proved stern monitors, bringing widespread injury and death to the denizens of many a fair garden; thoroughly testing the reputed hardiness of many rare exotics of recent introduction; killing outright many an old-established favourite; and destroying in several instances the one pet plant of some small garden in which it had flourished since that other time of abnormal cold—that fearful winter during the Crimean war. Amongst the lessons of adversity taught afresh in this time of trial, the necessity for greater attention to shelter, not only for gardens but in them, is of the greatest importance. Gardens in low-lying damp situations suffered most; and in such gardens shelter would probably prove of comparatively little use in very severe winters. No county has more favourable situations for gardens than Sussex, few so many. Hills and valleys abound throughout the length and breadth of it, and yet the occupants of many gardens less than 200 feet above sea level suffered severely by last winter's frost.

The garden here is on a southern slope of a range of hills termed the Forest Ridge in Mid-Sussex, the lower part of the garden being about 400 feet and the higher part of it about 500 feet above sea level. There is much shelter from trees upon its north and east sides, but I have found to my cost that trees alone do not often afford complete shelter from high winds. They certainly do serve materially to break its force; but unless there is a dense grove of them on rising ground that forms a semicircle behind the garden from east by north to west, cold blasts are very apt to rush in through openings and do much damage in winter and spring. The north-east corner appears to me to require especial attention, for I have much more reason to dread a visitation of cold wind from that quarter than from the north, for winds from the cardinal points are never so mischievous as cross winds, especially from the north-east and south-west. The first comes with its biting breath so frequently in spring, when the buds of blossom and foliage are bursting into beauty; and the other frequently at other seasons of the year, often blowing down trees and battering tender plants so much as to do serious injury. Not unfrequently the foliage of deciduous trees is so much bruised and lacerated by it in early summer as to retain traces of its ravages till the trees shed the foliage in autumn. Reverting

to the north-east wind, I have often told of its baneful effect upon the foliage of Peach and Nectarine trees in spring, and will now give an example of what it does in winter. Two fine specimens of *Arbutus Unedo*, both about 8 feet high and as much in diameter, stand near each other. One, well sheltered by a dense clump of timber trees with an undergrowth of Holly, is in perfect health and is now in full bloom; while the other, not 20 feet off, but just far enough outside the edge of the sheltering clump to feel the full force of the cold winds, is nearly killed. The *Arbutus* answers so admirably in our poor thin soil as to be worthy of all that can be done to shelter it. I also observe that a snug sunny nook contributes materially to its fruitfulness; and at this dull season of the year few objects in the garden are so attractive as a healthy specimen of it having plenty of the large scarlet berries mingled with the wax-like flowers.

I am sorry to have to record a failure with *Benthamia fragifera*, a worthy rival of the *Arbutus*, and which I have reason to think would answer equally well under precisely similar advantages of shelter and aspect. I had only one plant, and that was evidently too much exposed, for it suffered so much from the severe frost of 1878-9 that it died lingeringly in the following summer. *Fremontia californica* also perished in a very similar manner, but the plant was a weak one and much exposed. Both are worthy of all care—the *Fremontia* for its large golden flowers in spring, and the *Benthamia* for its scarlet fruit at this season of the year, and its handsome pyramidal form and free strong growth. Against a south wall *Abelia uniflora*, *Akebia quinata*, and *Berberidopsis corallina* have now been growing and flowering freely for eight years, all of them being so rampant as to require frequent pruning. On the same wall a *Ceanothus divaricatus* is equally flourishing, and yet a fine plant of it upon a west aspect was quite killed last winter, which shows the importance of not hastily condemning any plant or tree till it has been tried in various situations, and we have done all we could for it in the way of shelter.

For small gardens and for most shrubs raised artificial banks afford prompt and efficient shelter. If the soil is tolerably fertile 6 feet high will suffice, the bank soon being clothed with a dense growth, which ought always to consist of evergreens, such as *Rhododendron ponticum*, common Holly, Japanese Privet (*Ligustrum japonicum*), or *Mahonia aquifolia*. I have tried double Gorse and Broom, but do not recommend either for permanent growth, the first being liable to be crippled and spoilt by snow, and the Broom often becoming sickly or dying outright in a few years.

Undrained or badly drained soil often proves fatal to shrubs in winter. Attention to this is undoubtedly of equal importance to shelter. A deep fertile soil with plenty of stones in it and thorough subdrainage contributes materially to the health and longevity of trees and shrubs. Soil through which surface water passes quickly is always warmer than that which is badly drained either naturally or artificially. Frequent stirring of the soil, too, among young shrubs has a sweetening wholesome influence, admitting air and warmth, and inducing a much freer growth than when the surface is suffered to become hard and sodden. Frequently have I been successful by this simple process alone in infusing vigour and health into beds of young shrubs, the sickly stunted appearance of which

clearly betokened a want of attention or nourishment. The soil here, though remarkably silicious, is lamentably deficient of stones, and requires an extra amount of care and labour.

The lesson, then, taught by the late seasons of extraordinary cold and wet are never to make a garden in low-lying damp situations; to give the fullest attention to securing a warm aspect and abundant shelter; to thoroughly drain the soil; to impart mechanical division artificially if the soil does not possess it naturally; and to keep it well broken up among young trees and shrubs. Pray note that I do not advise frequent digging among old shrubs that are in a satisfactory condition of health, for then a firm unbroken surface is undoubtedly best. This remark also applies with equal force to fruit trees in full bearing. I have no latticework or expensive perforated iron over the paths of Peach borders, but I take good care that they are thoroughly fertile, and then make a walk of coal ashes upon them, trampling it as firmly as any other garden path.

Let there be plenty of cosy nooks among the shrubs too, open to the sunny south, but shut in from colder aspects; and here let us try at least two of every novelty of promise, and we shall be far more successful than when we plant them in less favourable situations.—EDWARD LUCKHURST.

GARDEN REFUSE AND ITS USES.

THE late Mr. Robert Fish, who was well known by his writings in this Journal, was deservedly admired for his advocacy of economy in garden management. Many things he would turn to good and profitable use which others were inclined to pass as worthless, and perhaps in nothing was this quality better exemplified than in the way he utilised the refuse of his garden. He used to say that the contents of a well-managed rubbish yard were a boon to any gardener, and so they undoubtedly are, as myself and many others have proved; yet to this day the importance of vegetable refuse is not fully appreciated by all cultivators, many of whom would rather trust to the scanty supply of farmyard manure, which, by-the-by, is in most cases difficult to obtain, than turn to good account the refuse which is daily collected from and around a garden. It is not difficult to have four or five different classes of well-decomposed soil at command for any purpose, provided care is taken to have the refuse overhauled once a month and a selection made of the various materials brought together.

The rubbish should be if possible placed in a yard in the back-ground and out of sight of much-frequented walks. There a process of burning and charring should be going on at intervals, according to the quality of the refuse, which will generally be in the greatest bulk during the autumn and winter months. All hard substances, such as prunings of hedges, fruit trees, shrubs, and the like, should be kept by themselves; sweeping of walks and drives also, because the seeds of weeds are sure to be present in such material. Short grass from the lawn, if not used for mixing with manure for hotbeds, should be laid with the leaves of vegetable crops to decay, and the refuse from under the potting bench should be first sifted, as it contains most of the best mixtures of soil; the finest may be laid aside for immediate use for common purposes, and the other placed with the coarser material for burning or decaying. Leaves of trees from the garden and pleasure grounds should be stored apart from other rubbish to make leaf soil for commoner use, or they may be added to the heap.

Having accumulated a sufficient quantity of materials, which may take one month, or it may be three—a little time should be devoted to their preparation—first of all a fire should be started with the coarsest substances to be burnt quickly if only ashes are required; but if to be charred only when the fire is well alight add some of the other rubbish or sweepings, which will steady it, and by that means a heap similar to that of burning charcoal may be made up to last several days, and in which almost anything can be charred or burnt. By this process no insect can live nor the seeds of weeds retain vitality, consequently it is the best way to reduce or purify such rubbish into a useable state again. The heap for decaying should be turned frequently, and at each alternate turning a portion of quicklime should be added, which will hasten the decomposition. When all is burnt or decayed the heap should be turned over, the charred material being separated from the other for special use, all the rest being thrown into a heap and well mixed so as to be ready for use when wanted, and it will be gratifying to the gardener to know that he possesses several tons of rich fertilising soil to add to any part of the garden

that stands in need of it, for such compost is more beneficial to many garden crops than pure farmyard manure would be.

Charred refuse and burnt soil form a first-rate mixture for adding to stubborn soils. It is very quick in its action, and a capital manure for the Onion bed, and is beneficial in a great degree when trenched in the ground for Carrots, Parsnips, Salsafy, Artichokes, Turnips, and other similar crops. It is better than the rich farmyard manure for the Broccoli crop, for it does not induce a too luxuriant growth, which should be guarded against in growing winter and spring crops of this vegetable. For summer Cabbages and Cauliflowers it is excellent, and is equally good for mixing in the soil for fruit trees, either when they are newly planted or root-pruned. For Asparagus beds it makes a substantial dressing, and for surface-dressing shrubbery borders and beds it is most useful; more especially when the shrubs are old and the soil almost exhausted by the roots, a surface dressing will have a marked effect. For flower beds, too, and borders, whether used for spring or summer bedding, or both, it is a valuable addition; but it must be employed with judgment, as some bedding plants will, by its application, be induced to grow too luxuriantly at the expense of flowering. It is, however, a good manure for Calceolarias, as I have often proved. Some of the best of it may be selected for mixing with loam for potting purposes, and nearly all bedding plants will thrive in it in pots. Sufficient, however, has been said to prove that the rubbish yard with its accumulated contents, commonplace as they may seem to be, is not to be despised and neglected.—THOMAS RECORD.

NOTES ON FRUITS.

SEVERAL of our Apple trees having cankered, died out, or refused to bear, are about to be replaced; and the communication of "WILTSHIRE RECTOR," November 18th, enabled me to decide on giving Stirling Castle a trial. With us Cellini does not canker, but bears freely large well-shaped and finely coloured fruit, which, when judiciously gathered and carefully kept, make excellent dessert fruit. So does Lord Suffield, but this year the clear golden hue has been disfigured by black specks. Many of the Marie Louise Pears have been deformed, drawn up like an S; few have been of good size or form or have attained richness of flavour. As to Jargonelle, our tree on a somewhat shaded western wall will not bear; it made me almost envious to read of it "fruiting so regularly and abundantly"—that most juicy, delicious, and graceful Pear, with tapering body and long slender stalk, as I remember it in former days. Our tree has been root-pruned; a great tap root removed. What more can be done? I am quite sure there is the soundest wisdom in the suggestion of "WILTSHIRE RECTOR," both as to fruit trees and to Rose trees, that few varieties, several specimens of each if you have room for them, proved to do generally well in a soil to them kindly and suitable, repays one far more satisfactorily than in after certain limits attempting to cultivate varieties with which the soil or situation disagrees.—A. M. B.

THE STAPLEFORD ROSES.

IN No. 17 of the Journal I notice an article on the Stapleford Roses, in which reference is made to an opinion given by me respecting these Roses. I think the writer must have partially misunderstood me, and I therefore will repeat my opinion there expressed, and add such observations as the little additional experience of the past season will prompt. From what I saw of the Stapleford Roses in England, as grown out of doors, I did not think that they would prove as valuable as had generally been expected; I found very few specimens that had opened well or that came in good form, and it seemed to be the prevalent opinion that they would not be of great worth for out-of-door culture. It is to be remembered, however, that these Roses have been forced and weakened by propagation, and that a trial of one year will not accurately determine their value for outside culture. Many excellent Hybrid Perpetuals, we find, make a poor show for the first year, that afterwards develop their true worth; and it is possible that some of these will act in the same way. While, therefore, I should not advise anyone to plant them largely out of doors, it is too early to condemn them as unfit for the open ground; it will take another season to determine their worth for this purpose.

As Roses for forcing under glass, I regard them as worthy of the highest esteem. There are few among the Teas that will give the same quantity of fine blooms during the winter that these do. All of them are to be prized for culture under glass, excepting Jean Sisley, Nancy Lee, and perhaps Viscountess Falmouth. Two of these varieties do not open well, and if the former prove a valu-

able variety it will be out of doors only. But of the others we have had very many fine blooms from plants grown in pots, and more especially from those budded on a large plant of Solfaterre. This makes a capital stock, and I advise anyone having plants of Solfaterre to bud in some of the Hybrid Teas. The dark ones, Hon. Geo. Bancroft and Duke of Connaught, will prove, I think, the most valuable; but all the rest, excepting Jean Sisley and Nancy Lee, are promising Roses, and I think no one will make a mistake in procuring them in quantities for the purpose of growing under glass. Those that I like the least are Nancy Lee, Jean Sisley, Beauty of Stapleford, and Duchess of Westminster, none of them being fragrant. Hon. Geo. Bancroft, Duchess of Connaught, and Viscountess Falmouth are all highly scented; this adds greatly to their merit. Michael Saunders and Pearl have also an agreeable perfume, the latter with a decided Bourbon odour. Duke of Connaught has no odour, but is of good form and a fine crimson colour, making a decided improvement on Duchess of Edinburgh.—H. B. ELLWANGER.

GROWING GRAPES WITHOUT FIRE HEAT.

I HAVE many times seen particulars in the Journal concerning the advantages of growing Grapes without fire heat, and that has induced me to give a brief description of my own success in that way. I first wish to acknowledge that I owe all my success to the instructions upon the subject contained in the Journal, for a few years ago I knew but little of Vine culture. My vinery is a span-roof house extending east and west; it is 64 feet long, with a partition in the centre. The Vines are planted inside in a border 4 feet 6 inches wide, the outside border being 6 feet wide. Every year I train up a young rod and cut out the old one, because I find the young rod succeeds best, allowing a length of 6 feet to each.

The following varieties are growing in the early house:—Early White Malvasia, a good Grape, but the berries are very irregular in size; Duc de Malakoff is a good early variety, but the berries are not large; both berries and bunches have, however, been larger this year than we ever had them before. Chaptal is a good bearer with very large bunches, and keeps well; a fine white Grape. Le Sucre is a satisfactory white variety, fruit very juicy and sweet. Black Hamburg is useful, but some of the Grapes turn sour, though this year they are not nearly so bad. Trentham Black is an excellent variety; it has one defect—like Early White Malvasia, the berries are very irregular. White Tokay has large bunches and sets well, almost too well, as there are so many to cut out at thinning, but the fruit does not keep so well as some others. We had 136 bunches of good size in this house. In the second or later house the undermentioned varieties are grown:—Calabrian Raisin I cannot speak favourably of, as the berries always crack. I had three Vines at first, then two were destroyed, and the other tried once more, but with no better success, so that is now removed. Bowood Muscat is excellent; the bunches are very large—from 9 to 12 inches long, and ripened well this year. Lady Downe's is a useful late Grape, as it sets and bears well in our cold house, but the berries are not large. Mrs. Pince's Black Muscat is an excellent Grape; bunches very long, many a foot in length. Last year there were many small berries, due, I expect, to the cold weather; but this year I closed the house earlier, and there is a fine crop. Another Grape here is called Muscat Escholata, but incorrectly, as it is a black variety and late. The berries are large and very even, and they set well; it is distinct from Lady Downe's. We have a better crop of Grapes this year than ever we had before, for we had 236 bunches in the second house. I was informed a short time since that I could not grow Grapes without fire heat, but my informant was greatly surprised to see this house with 236 bunches well coloured.—F. WALKER.

[The Grapes are very useful table fruit, Mrs. Pince's Muscat being of excellent quality. The variety named Muscat Escholata is, we think, Gros Guillaume.—EDS.]

LILY OF THE VALLEY.

UNDER this heading, on page 453, Mr. Bardney has given some very instructive notes, and has, in fact, left but little to be said on the subject of forcing this beautiful flower. That the Lily of the Valley is one of the most popular flowers grown is not surprising, as it really possesses more desirable qualities than any plant with which I am acquainted. Imported roots at times are extremely disappointing, as not only will they not flower during November and sometimes December, but instances have come under my notice where they would not start at all. This failure, as Mr. Bardney suggests, may probably be owing to the crowns being badly ripened, and therefore liable to be irrecoverably injured by hard

forcing. They might have been started too early, but the first week in January can scarcely be called early; or they might have been placed in too strong bottom heat, and other reasons have been suggested as the cause of failure. It is quite certain something was radically wrong, as they never started, although the crowns remained for twelve months in apparently as fresh a condition as when received.

Imported clumps are often received in a hard dry state, and I am inclined to think are often either fatally injured or materially weakened by potting them in such a state, as they are never thoroughly moistened. My practice with such dry clumps is to place them in a tub of water till saturated, allowing them to drain during a night, and prior to potting loosening the bottom and sides of the ball with a pointed stick. Then, again, rather than pot high, should the balls be too long I prefer reducing them, as moisture the roots must have. Properly potted and plunged in a gentle hotbed composed principally of leaves and covered with some of the fermenting material, they will generally flower freely enough early in the year.

In my estimation well-prepared home-grown crowns are preferable for forcing, and frequently give as strong blooms as the imported clumps. If well-established beds are available for the work, it is the best plan to lift large flat square clumps of roots, placing them in ordinary bedding Pelargonium boxes, and adding a little good soil about the roots. The boxes can be placed on hotbeds in the early vineries or forcing pits at intervals according to the demand. If plants in pots are required for any particular purpose, when the blooms are expanding the roots may be taken out, carefully divided into the sizes required, and potted off, working in a few single pieces wherever requisite for symmetry. Good even pots can thus be had without any injury accruing to the bloom. One box of crowns will yield a great quantity of cut blooms with a small amount of trouble. An open position and a rather strong clayey loam suits the Lily of the Valley admirably, and a plot a few feet square would supply clumps for lifting, and also a number of late blooms sufficient for most establishments. Some roots must be replanted every season, and for this I prefer using either the latest forced crowns, or, better still, some of the weakest, planting single crowns rather thickly and irregularly prior to the commencement of growth. The Lily of the Valley is a moisture-loving plant, and will repay a mulching of manure given at the present time, or before growth commences.—W. IGGULDEN.

POTATO DISEASE AND RAINFALL.

"INTERLOPER" has not replied to my queries with regard to the rainfall theory of the Potato disease, and thinks that it is bad logic on my part to ask him to do so. I do not see that. One of the first axioms of Euclid is that things which are equal to the same thing are equal to one another, and "INTERLOPER" in a late number of the Journal asks the advocates of the fungus theory, of which I am one, to harmonise certain facts with that theory of disease, and it is only fair, I think, to ask him to follow suit. He pleads want of time to work up the matter, but the real truth is no amount of time would be of any avail. The rainfall theory is unsound, and the difficulties with regard to it are so many that it cannot be entertained.

Amongst all the scientific witnesses examined before the Royal Commission I do not remember one who did not regard the fungus, the *Peronospora infestans*, as the only true cause of the malady. This fungus is closely allied to the family of the *Saprolegniae* which only flourish in water, therefore it is not to be wondered at that it progresses much more rapidly in wet weather; and being a native of Bogota and other places on the western coast of South America, a warmer climate than ours, it also likes warmth. Bearing in mind these facts and a few others with regard to the disease, everything can be satisfactorily explained and the parts fitted together like the pieces of a Chinese puzzle.

I will now refer to a few of "INTERLOPER'S" queries. "The outside roots of a row and the outside rows of a patch or field always give a larger proportion of sound tubers than the inside rows." I have not found this invariably the case; but admitting that such is generally the case, the outside rows have the advantage of more air and light, and when a patch of Potatoes is diseased and throwing off the spores of the fungus, the Potatoes on the outside rows are like an army which is protected on one flank by a morass—they can only be attacked on the other. "The rows of Potatoes grown over a rubble drain gave sound tubers when the adjoining rows were nearly all diseased." This can be readily accounted for by the greater dryness of the soil producing a healthier growth in the stems of the Potato, so that when

attacked by the fungus it would not make way on the tissues of the plant with anything like the same rapidity it would on those grown in a damper soil; and the extra dryness of the soil would also act in another way, by preventing the disease spreading from tuber to tuber in the soil. The earth when dry is an excellent deodoriser, but when sodden with wet the effect is almost entirely lost. The rows grown on land sheltered from rain by the Scarlet Runners were probably less diseased from the same reason as mentioned above. And with regard to "roots grown close to a coarse-growing weed, such as fat hen, invariably giving sounder tubers than other roots in the same patch," I believe this comparative immunity arises from the large weeds keeping off the seeds of the fungus to a certain extent like an umbrella. But my own experience with regard to weeds is somewhat different from that of "INTERLOPER." Sometimes a root appears all the better for being partly protected by weeds, at others worse, but the weeds have been of a smaller kind. Generally speaking I should prefer the weeds removed, as interfering with the proper evaporation of moisture from the soil, and thus tending to aggravate the malady rather than produce a beneficial effect.—AMATEUR, Cirencester.

CHRYSANTHEMUM SHOWS.

KINGSTON AND SURBITON.

THIS important Chrysanthemum Society held its annual Exhibition in the large Drill Hall, Kingston, a highly satisfactory display being produced. Semicircular groups of decorative plants alternately arranged with Chrysanthemums and collections of specimen plants were placed near the walls, while the centre of the spacious building was occupied with long tables of cut flowers and fruits and a large collection of graceful table plants. The arrangements generally were very creditable to the painstaking and energetic Secretary, Mr. Thomas Jackson. The unpropitious weather of the first day prevented many from attending, but on the second day the weather was better, and a larger company attended than on any former occasion. Among the liberal prizes offered for Chrysanthemums were the challenge vase, value twenty-five guineas, won in 1879 by Mr. Harding, gardener to J. D. Galpin, Esq., Putney; two handsome clocks, and a silver watch, each of the value of four guineas. The schedule of prizes was most comprehensive and carefully compiled, open to every subscriber, and so arranged that a competitor in the larger classes is prevented from competing in the smaller classes, thereby bringing a greater number of successful exhibitors and a finer display.

Groups.—The best arranged group of miscellaneous plants, flowering, and foliage for effect, was from Mr. King, gardener to R. Few, Esq., Wolsey Grange, Esher; it was most tastefully and admirably finished, and contained very fine decorative Crotons, Palms, Ferns, Eucharis, and Primulas. Mr. C. Attrill, gardener to C. J. Freake, Esq., Bank Grove, Kingston, and Mr. Croxford, gardener to Mrs. Dunnage, Allbury House, Surbiton, were second and third respectively, all exhibiting good collections. Messrs. Jackson also staged a large collection of flowering and foliage plants. The groups of Chrysanthemums arranged in a space of 50 square feet were no improvement on the past. The best, both for quality and effect, came from Mr. C. Bond, Orford House, Ham; the second prize was awarded to Mr. J. Buss, gardener to Mrs. Price, Parkside, Ewell, for a very crowded and non-effective collection; the third went to Mr. J. Otley, gardener to G. F. Belville, Esq., Lismaine, Surbiton, who, in the opinion of many visitors, should have been placed second; fourth to Mr. T. Luff, gardener to H. Evill, Esq., Worcester Park; and an extra prize to Mr. R. Watson, gardener to T. H. Bryant, Esq., Surbiton.

Plants.—In the class for six trained specimen large-flowering plants, the collections exhibited by Messrs. King and Beckett attracted much attention from their enormous size (some being nearly 5 feet in diameter), the number of flowers, and the regularity of their training. The first prize, consisting of a silver watch value four guineas, was awarded to Mr. King, the varieties represented being *La Nympe*, with 136 perfect blooms; *Prince of Wales*, Mr. G. Glenny, Mrs. Dixon, Mrs. G. Rundle, and *Hero of Stoke Newington*—all healthy and remarkably well flowered. Mr. Beckett, gardener to J. P. Currie, Esq., Sandown House, Esher, took second honours with a handsome collection, the plants not quite so large as the first-prize collection, but in one or two instances the blooms were larger. All were well grown, particularly *Prince Alfred*, *Prince of Wales*, *Julie Lagravie*, and the trio of the *Rundle* type. Mr. R. Watson received the third prize. For three plants Mr. W. Burns, gardener to H. A. Rigg, Esq., Wykeham Lodge, Horsham, and Mr. J. Child, gardener to J. Gray, Esq., Claygate, were first and second respectively; while in the class for three standards Messrs. Beckett, Watson, and J. Child were placed in the order of their names. The standards were very healthy, but tied rather too late. Some very large and profusely flowered single specimens were exhibited; Mr. King being first with a grand Mrs. Dixon, Mr. Beckett second with a good *Prince of Wales*, and Mr. Burns third with Mrs. Dixon.

Pompons were good. For six trained Mr. R. Watson was the most successful with *Cedo Nulli*, *Fanny*, *Antonius*, *Salamon*, *Helena*, and *Marquis de Coix*. Mr. Lyne, gardener to A. Schlusser, Esq., was a praiseworthy second with plants naturally grown and very profusely bloomed; a good plant of *Dick Turpin* was very conspicuous. For

three plants Mr. J. Watson, gardener to Captain Cundy, Norbury House, Surbiton, was the only exhibitor, and was awarded the first prize. Three standards were exhibited by Messrs. Lyne and R. Watson, who were placed in the order of their names. Mr. Lyne's collection was *Rosinante*, *Dick Turpin*, and *Bijou d'Horticulture*, very large heads and surprisingly abundant blooms. Mr. R. Watson's single specimen *James Forsyth* was especially noteworthy, while Mr. Lyne and Mr. Curtis occupied the second and third positions with good plants.

Cut Blooms.—These were, taken collectively, remarkably fine and numerous. About 1200 blooms were staged, the Japanese being fine and in large numbers. The great centre of attraction was in the competitive class for the champion challenge vase mentioned above, for which there were seven competitors. The prize was given for forty-eight *Chrysanthemum* blooms, twenty-four incurved and twenty-four Japanese, shown on separate boards. Mr. Tunnington, gardener to C. MacIver, Esq., Calderstone, Liverpool, staged the premier collection, the majority of the blooms being of excellent form. The twenty-four incurved varieties were faultless; some few of the Japanese were not as large as in some of the other collections, but the weight and superiority of the incurved varieties more than balanced the little that was wanting in the Japanese collection. This was altogether a handsome collection, and well merited its position. The varieties were *Queen of England*, *Prince Alfred*, *Empress of India*, *Inner Temple*, *Novelty*, *Golden Empress of India*, *Prince of Wales*, *John Salter*, *Princess of Wales*, *Venus*, Mrs. Heales, *Jardin des Plantes*, *Beauty*, *Nil Desperandum*, *Sir Stafford Carey*, *Lady Hardinge*, *Lord Derby*, *White Beverley*, Mrs. Dixon, *Princess Beatrice*, *White Venus*, *Hero of Stoke Newington*, *George Glenny*, Mrs. G. Rundle, *Japanese*, *Elaine*, *The Sultan*, *Peter the Great*, *Fair Maid of Guernsey*, *Chang*, *Soleil Levant*, *Meg Merrilees*, the finest bloom of the variety in the exhibition; *Bismarek*, *Comtesse de Beauregard*, *Fleur Parfait*, *L'Incomparable*, *Hero of Magdala*, *Mdlle. Moulix*, *Cry Kang*, *Apollo*, *Nuit d'Automne*, *La Nympe*, and *Baronne de Prailly*, more like *Gold Thread*; M. Crousse, *La Frissure*, *Arlequin*, *Fulgore*, and *Laciniatum*. Mr. G. Harding, gardener to J. D. Galpin, Esq., Putney Heath, was awarded the second place. Most of Mr. Harding's Japanese blooms were decidedly larger and superior to the first-prize collection, but in this collection there were two or three weak varieties—an *Elaine* and a *Red Gauntlet* that displayed a very prominent eye, though most of the others were most praiseworthy; but in the incurved section this collection was decidedly many points inferior, the best being *Princess of Wales*, *Nil Desperandum*, *Prince of Wales*, Mr. Brunlees, and *Yellow Perfection*. *Sarnia*, *Meg Merrilees*, *Baronne de Prailly*, *Sultan*, *Nuit d'Hiver*, *Oracle*, *Fanny Bouchard*, *Gloire de Toulouse*, *Fulton*, and *Fulgore* of the Japanese were magnificent. Mr. Gibson, gardener to J. Wormald, Esq., Morden Park, Mitcham, was placed third; his collection of twenty-four varieties of Japanese were decidedly the best collection, taken collectively, in the exhibition, but his incurved varieties were weak. Mr. Gibson's *Criterion*, *Fair Maid of Guernsey*, and *Baronne de Prailly* were extremely fine. Mr. King was placed fourth, and an extra prize was awarded to Mr. McPherson, gardener to J. Page, Esq., Surbiton, all exhibiting very creditable collections, and thus this handsome trophy goes to the north for the present.

The superiority of Mr. Tunnington's incurved blooms was again displayed in the class for twenty-four distinct, for he was a long way ahead of the other four competitors. Messrs. Beckett, E. Berry, and Croxford were placed second, third, and fourth respectively. For twelve incurved blooms there were nine collections staged. Mr. J. Hill, gardener to A. Savory, Esq., Potter's Park, Chertsey, was a very good first with a remarkably neat and even collection. Messrs. J. Lyne and Burns took second and third prizes in that order. For six blooms Mr. H. Smith, Waverley Abbey, Farnham, and Mr. T. A. Benson, gardener to W. S. Roots, Esq., Kingston, shared the honours between them.

A maiden class was provided, which brought nine exhibits; Mr. H. Smith being placed first, Mr. C. Slade, gardener to Lady Bowater, Richmond Park, second, and Mr. J. Martin, Surbiton, third.

Japanese blooms were numerous. In the class for twenty-four distinct varieties there were ten exhibitors, the finest collection being exhibited by Mr. Beckett, who won a timepiece, value four guineas, with a handsome, even, and brilliant collection comprising *Chang*, *Baronne de Prailly*, M. Bellew, *Hiver Fleur*, *Magnum Bonum*, *Soleil Levant*, *Oracle*, *Alba Plena*, *Triomphe du Nord*, *Grandiflora*, *Striatum*, *Fulgore*, *Nuit d'Hiver*, *Sarnia*, *Bouquet Fait*, *Mdlle. Moulix*, *Orphée*, *The Daimio*, M. Ardene, and *Peter the Great*. Mr. Lyne's was a very good and close second; Mr. Hinnell, gardener to F. A. Davis, Esq., Surbiton, third, Mr. Harding fourth, and to Mr. Watson an extra prize was awarded.

For twelve Japanese Mr. Hill was deservedly awarded the first prize, Messrs. Burns and Berry being placed second and third respectively.

Anemones were numerous exhibited, Mr. Hill being well to the front with Mrs. Pithers, *Queen Margaret*, *Acquisition*, *Prince of Anemones*, *Gluck*, *Fleur de Marie*, *Louis Bonamy*, and a fine flower of *Lady Margaret*. Messrs. Berry, Gibson, and Hinnell were the other successful exhibitors in this class. Reflexed blooms were also plentifully staged, Messrs. Watson, Hill, and Child being placed in the order of their names.

Other successful exhibitors of Chrysanthemums were Messrs. Smith, Bolt, Pacey, and Press.

Many elegant collections of table plants were staged, the best nine being exhibited by Mr. Smith, Oakfield, Wimbledon Park; they were very graceful, bright, and handsome. Messrs. Watson and Beckett, who were second and third, exhibited well for six plants; Messrs. Lyne King, and Luff were placed in the order of their names. Berried plants, Primulas, and fruit were also well shown.

BOROUGH OF HACKNEY.

The thirty-fifth Exhibition of this old-established Society was held in the Royal Aquarium, Westminster, on the 17th and 18th inst., a fine display being produced, although the cut blooms were less numerous than in the previous year. A handsome bank of plants at the north end of the building in front of the great organ formed by far the most effective portion of the Exhibition, as the majority of the specimens were bearing a large number of blooms, any imperfections of which in size and form were not noticeable at a short distance, the colours being as bright and as well arranged as could be desired. In the gallery there were also some good collections of fruit and vegetables, among the former the Pears and Apples being especially fine and abundant, while Potatoes were strongly represented. The general quality of the cut blooms in the numerous classes was satisfactory, but not unusually good, except in a few of the leading collections entered in the most important classes, where some handsome examples were staged, particularly in competition for the silver cups. Several fine stands of Japanese varieties were contributed in the open classes, so near in merit that the Judges experienced much difficulty in determining the winners. The schedule enumerated thirty classes, the first twenty-two of which were devoted to Chrysanthemums—cut blooms and specimens—twelve being open and ten confined to growers in the Borough of Hackney, and the remaining eight (open) provided for the exhibition of fruit and vegetables.

Commencing with the Chrysanthemums, one of the principal classes was that for a group of plants arranged for effect in a space of 100 square feet. Three handsome prizes were offered—the first, a silver cup valued at £5 given by the Royal Aquarium Company, the second £3, and the third £2. Four competitors appeared, and their exhibits constituted the chief part of the bank already referred to. The cup was awarded to Messrs. Mayhood & Sons, Windsor Nurseries, Lower Richmond Road, Putney, for an effective group of fairly good plants, the varieties numerous, well selected, and the arrangement tasteful. Such striking and showy varieties as Striatum, Dr. Sharpe, Julie Lagravère, and Empress of India with the Rundle family were most noticeable. Mr. G. Stevens, St. John's Nursery, Putney, followed with a similar group, the blooms being fine, but dark colours predominated rather too much. The third position was secured by Mr. Butcher, gardener to R. Glover, Esq., The Priory, Hadley, Barnet, with well-grown plants bearing a profusion of flowers, but the arrangement was not so good as in the preceding, dwarfs and standards being somewhat irregularly placed. The premier award for six large-flowering varieties, dwarf plants in 12-inch pots, was easily obtained by Mr. W. Hall, gardener to J. Stevens, Esq., Tulse Hill, who staged clean healthy specimens, remarkable both for the fine foliage and blooms. Mr. Brunlees, Lady Hardinge, Mrs. Dixon, and Mrs. G. Rundle were the best. Mr. G. Dray, Southgate Nursery, Kingsland, was the only other exhibitor in that class, and was accorded the second prize for moderately good plants. The standard large-flowered varieties were not in excellent condition. Mr. Butcher's premier collection of four were rather loose but bore large and numerous blooms, while those placed second, from Mr. Prickett, gardener to Mrs. Bowerbank, Stoke Newington, though much more neatly trained, were deficient in the blooms; and the same may be said of the third-prize specimens from Mr. F. Wells, gardener to W. A. Smee, Esq., The Limes, Woodberry Down. Mr. Butcher was again successful in obtaining the chief prize for six dwarf Pompons in 9-inch pots. His plants were very healthy and profusely flowered, the most noteworthy being *Mdlle. Marthe*, *Fanny*, *White Cedo Nulli*, and *St. Michael*. Mr. F. Wells was a good second with clean specimens of the *White* and *Lilac Cedo Nulli* and *Mr. Astie*. Mr. Howes, gardener to Mrs. Bennett, Tulse Hill, was third with a fair collection. In the borough classes there was not a very large display, although the specimens were exceedingly well grown generally. The principal class was that for ten plants in 12-inch pots, the Royal Aquarium offering the first prize—a silver cup—which was awarded to Mr. Prickett for good specimens that were noted in our report of the Stoke Newington Show last week, where they also gained a similarly high position. Mr. S. Gilbey, gardener to B. Booth, Esq., was a good second with some fine standards.

Cut blooms, as we have indicated, were not quite so numerous as at previous exhibitions of the Society, but creditable examples were staged in all the chief classes. For twenty-four incurved blooms in the open class four prizes were offered—namely, a £5 silver cup by the Society as the first, £1 as the second, 15s. as third, and 10s. fourth. The difference between the first and second prizes in this and several other classes was very disproportionate. Five collections were staged, all possessing more than ordinary merit. E. Sanderson, Esq., Felix Villa, St. Mary's Road, Willesden, the President of the Society, was the winner of the cup with even and remarkably symmetrical blooms, including the following varieties admirably represented—*Princess of Wales*, *Cherub*, *Golden George Glenny*, *Refulgence*, *Emily Dale*, *Nil Desperandum*, *Lady Hardinge*, *Abbé Passaglia*, *White Venus*, *St. Patrick*, *Golden Empress of India*, *Plenipo*, *Yellow Beverley*, *Venus*, *Mrs. George Rundle*, *Empress Eugénie*, *Isabella Bott*, *Princess*

Beatrice, *Mr. Brunlees*, *John Salter*, *George Glenny*, *Prince Alfred*, *Mr. Bunn*, and *Incognito*—a very good selection and well staged. Mr. C. Gibson, Morden Park, Mitcham, followed very closely, his collection including blooms of fine substance but not quite so even generally as the first, though many of the blooms were much larger. Among those especially noteworthy were *Lady Slade*, *Baron Beust*, *Lady Talfourd*, *Queen of England*, and *Golden Empress of India*. Mr. E. Berry, The Gardens, Roehampton House, and Mr. W. R. Strong, gardener to Mrs. D. Reid, Virginia Water, were third and fourth respectively with neat and fresh blooms. In the same division the competition was extremely close in the class for twelve incurved blooms, no less than seven collections being staged. The premier award was secured by Mr. E. Berry with even specimens of first-rate varieties; the remaining prizes being obtained by Mr. C. Fewell, gardener to J. C. Lanyon, Esq., Birdhurst, South Croydon; Mr. J. Ridout, gardener to J. Haywood, Esq., Woodhatch Lodge, Reigate; and Mr. Bones, gardener to David McIntosh, Esq., Havering Park, Romford. Seven exhibitors also appeared with six incurved blooms; Mr. C. Berry taking the first position, followed by Messrs. Fewell; C. Herrin, Chalfont Park; and A. Wright, gardener to G. Brightwen, Esq., The Grove, Great Stanmore. Large-flowered Anemone varieties were shown in handsome condition by Messrs. Gibson, Berry, and Fewell, who secured the chief prizes, while Anemone Pompons were equally well contributed by Messrs. Butcher and Fewell. In the open class for twelve Japanese varieties there was a magnificent display, the prizes being similar to those for twenty-four incurved blooms. There were nine collections, all containing unusually fine blooms, the colours bright and pure and the varieties well chosen; indeed the class was considered by many judges to be the best in the Exhibition. Mr. C. Gibson succeeded in obtaining the cup with beautiful examples of *Fair Maid of Guernsey*, *Bouquet Fait*, *Fulgore*, *Incomparable*, *Elaine*, *Baronne de Prailly*, *Grandiflora*, *Meg Merrilees*, *Red Dragon*, *Criticon*, *Ethel*, and several others. Mr. G. Harding, gardener to J. D. Galpin, Esq., Putney Heath, followed very closely with handsome blooms. Messrs. Mayhood & Son were third, and Mr. R. Strong fourth, exhibiting very creditably. In the borough class for twenty-four incurved blooms the best were from Mr. Langdon, gardener to Messrs. Munroe & Adams, Brook House, Clapton; Mr. Martin, gardener to F. Appleford, Esq., The Cedars, Woodberry Down, and Mr. J. Holmes, gardener to J. Hicks, Esq., Manor Lodge, Clapton, taking the second and third prizes with neat blooms. The same exhibitors with Mr. W. Holmes also carried off the prizes for six and twelve incurved blooms, while Japanese were fairly well represented by R. Ballantyne, Esq., Linton Lodge, Victoria Park Road.

Fruit was staged in abundance, the Apples and Pears being particularly numerous. Mr. J. Ridout had the best black Grapes, easily securing the first prize with medium-sized bunches of *Black Alicante* extremely well coloured; Mr. J. Wallis, gardener to the Rev. W. Sneyd, Keele Hall, Newcastle, Staffs, taking second with *Gros Guillaume*, fairly good; Mr. J. Goldsmith, Sandhills, Bletchingley, following closely with the same variety. White Grapes were poor. Mr. Bennett, Rapley, sent some fine bunches of admirably finished *Black Alicante*, not for competition, which were highly commended. Dessert Apples were represented by eight collections, very even and of good size. Mr. Ross, gardener to C. Eyre, Esq., Welford Park, Newbury, was placed first with good *Ribston Pippins* and *Scarlet Pearmain* among others; Mr. Fanning, Roehampton, and Mr. Fowle, gardener to Sir H. Mildmay, Dogmersfield Park, Hants, taking the remaining prizes. A similar number of collections of culinary Apples were contributed, also in good condition, Messrs. Ross, Dean, and Fowle taking the prizes in the order named. Pears were remarkably large and well ripened, the premier collection of dessert varieties from Mr. Fowle attracting much admiration. *Duchesse d'Angoulême*, *Doyenné du Comice*, *Glou Moreau*, *Chaumontel*, *Beurré Bachelier*, and *Pitmaston Duchess* were the varieties, all in grand form. Messrs. Dean and W. Hall secured the second and third prizes. In addition to the competing exhibits Mr. John Watkins of Hereford contributed about sixty varieties of Apples, and the General Horticultural Company (Mr. John Wills) had a tasteful arrangement of fine fruit, vegetables, and flowers.

Vegetables were shown in fine condition by several exhibitors. There were seven collections in the class for not less than eight varieties of vegetables, all of which were very creditable. Mr. Austin, gardener at Ashton Court, Bristol, secured the premier award with a generally excellent assortment. His best dishes were *Orange-field Tomatoes*, *Telegraph Cucumbers*, *Tripoli* and *Reading Onions*, *Carter's Stratagem Peas*, *Lapstone Kidney Potatoes*, *Veitch's Autumn Giant Cauliflower*, and *Snowball Turnips*. Mr. W. Iggulden, Orsett Hall Gardens, Romford, followed very closely with good examples of *Trophy Tomatoes*, *Carter's Perfection of Beets*, *Carter's Jersey Lily Turnips*, *Snowflake* and *Beauty of Kent Potatoes*, and *Sutton's Improved Reading Onions*. The third prize was awarded to Mr. Herrin for a very even clean collection. The two Potato classes were well filled, many of the leading Potato growers exhibiting. Nine collections of twelve dishes were staged, and the competition was very close. Mr. R. Dean obtained first honours with very clean medium-sized examples. Mr. C. W. Howard of Bridge, Canterbury, was an excellent second, and Mr. Ross, Welford Park Gardens, was awarded the third prize. There were seven collections of six varieties, the prizetakers being Mr. C. W. Howard; Mr. Miller, gardener to the Marquis of Donegal, Newbury; and Mr. R. Dean.

Messrs. James Carter & Co., London, exhibited large heaps of Magnum Bonum, Scotch Champion, and a very great variety of other Potatoes in good condition, and also a collection of vegetables, which included well-grown examples of Model Cucumber, Perfection Brussels Sprouts, Pinesfield Improved White Spanish Onion, Perfection of Beets, Mont Blanc Cauliflowers, and several more of their specialities. Messrs. Sutton & Sons brought fine heaps of their Magnum Bonum, Reading Abbey, Woodstock Kidney, and Redskin Flourball Potatoes, and a general collection of leading varieties, which comprised good dishes of Purple Blush, Red Fluke, International, St. Patrick, Yorkshire Hero, Vicar of Laleham, and other popular varieties. Messrs. Charles Lee & Sons, Hammersmith, also exhibited a good collection of Potatoes, which included a large heap of the new Defiance Seedling, Hammersmith Kidney, Wonderful, Pride of America, Blanchard, and Late Rose.

Among the special exhibits in the central hall were collections of handsome Pelargonium blooms and Salvias from Mr. H. Cannell, Swanley, Kent, that formed a bright little group, backed up with plants of the graceful *Prenanthes elegantissima*. Mr. Biggs of Lewisham was awarded a special prize for enormous dwarf-trained specimen *Chrysanthemums*, fairly well flowered but rather coarse; and Mr. Peachey, Stamford Hill, sent blooms of the *Chrysanthemum Angelina*, for which a first-class certificate was awarded, as at Stoke Newington. The general arrangements were very satisfactory, and highly creditable to Mr. W. Holmes, the Secretary, except in the system adopted of writing the prize cards out after the judging, which, as we alluded to last year, caused considerable delay.

CROYDON.

This Society held their fourth annual autumn display on Friday and Saturday last in the small Public Hall. In the plant classes there was a decided falling-off, although several of the groups were very attractive. The cut-flower classes were above the average, the vegetable and fruit very fine. Mr. Gibson, gardener to J. Wormald, Esq., Mitcham, obtained the premier award for twelve incurved blooms and twelve Japanese blooms. His collection was very fine, some of the blooms being those he exhibited at the Aquarium a few days previous. Mr. C. Welstead, gardener to Mrs. Lodge, Bramley Hill, Mr. C. Roffey, and Mr. H. Reed were among the prizetakers for groups of *Chrysanthemums*; while Mr. J. Fewell, gardener to C. J. Lanyon, Esq., Birdhirst, was a successful prizetaker in a dozen classes. Mr. C. Orchard, gardener to F. W. Harris, Esq., Coombe House, also exhibited very largely, and was awarded several first prizes; Messrs. Elsey, Johnson, and Brice exhibited well and obtained several prizes. The arrangements were well carried out under the superintendence of Mr. C. Roffey, the Secretary.

MAIDSTONE.

On Friday last the 19th inst. this Society held its annual Exhibition of *Chrysanthemums* and fruits in the Corn Exchange of Maidstone; and although the former were neither so numerous nor of such quality as might have been expected from the liberal prizes offered, yet the magnificent Apples and Pears staged in the fruit classes compensated to a great extent for the deficiency. It is remarkable that in one of the best districts of favoured Kent *Chrysanthemums*, both plants and cut blooms, should be exhibited in some instances inferior to those produced by such urban societies as Stoke Newington and Lambeth, where the members have all the disadvantages to contend with that a smoke-laden atmosphere can occasion. This is still stranger when it is considered the prizes offered at Maidstone in the chief classes far exceed those at the majority of *Chrysanthemum* exhibitions. Every possible encouragement was given both to growers in the district and to those of England generally, but with comparatively poor results. The reason for this it is not easy to discern, but it certainly appears that in one portion of the kingdom at least this deservedly popular plant does not receive the attention it merits.

The large hall of the Corn Exchange was devoted to the *Chrysanthemums*, and considering the few entries the arrangement was all that could be expected. Had there been three times the number a much better effect would have been produced, for some difficulty was evidently experienced in disposing the exhibits so as to occupy the space at command, the plants being arranged near the walls and the cut blooms on the long central table. The principal of the plant classes was that for twelve large-flowering varieties, in which the first prize was a silver cup, value five guineas, presented by Lord Holmesdale. The best collection, not only in that class but in the whole Exhibition, was from the Rev. C. W. Shepherd, Trottscliffe Rectory, Maidstone, and Honorary Secretary of the Society, to whom the cup was awarded. The plants were healthy, well clothed with foliage, and bore numerous but rather small blooms. Golden George Glenny was a handsome specimen, fairly well trained and of good size, the blooms being neatly formed and abundant. Other noteworthy varieties were Golden Christine, Pink Venus, Hereward, and Mrs. G. Rundle. The second position was accorded to plants from H. A. Brassey, Esq., M.P.; these also were vigorous and fresh but rather irregular, the most compact being a specimen of Vesta. T. Phillips, Esq., West Malling, was third with even plants, but in rather poor condition. For six plants of incurved varieties Charles Neve, Esq., Chart Sutton, was placed first with examples of the Empress of India bearing handsome blooms; J. W. Braddick, Esq., Broughton Mount, and W. J. Newberry Esq., Leeds, taking second and third. Mr.

Neve also had the best single specimen—namely, Mrs. G. Rundle, moderately well flowered. The Rev. C. W. Shepherd exhibited the only collection of six Japanese varieties, and secured the chief prize for specimens of The Cossack, Mons. Lemoine, Peter the Great, and Elaine flowering profusely, the latter especially, though the blooms were not of excellent form.

But little more can be said in favour of the cut blooms than of the plants, for there was scarcely a first-rate collection staged. The class for thirty-six incurved blooms was open to all England, a handsome silver cup value ten guineas constituting the first prize, £4 the second, and £2 the third, which might have been expected to insure a large number of entries and keen competition; this was not the case, however, for only two collections appeared, and the Judges must have had very little difficulty in determining their relative position. Mr. J. Hillier, Wandsworth, gained the cup with blooms of medium size, moderately good in form and substance, but well staged. Some of the best in the stand were Princess of Wales, Golden Empress of India, Nil Desperandum, and Nonpareil. The second prize was awarded to A. Warde, Esq., West Farleigh, who had rather irregular blooms, though the Rundles were fine. C. N. Kidd, Esq., Dartford, exhibited the finest of the three collections of twenty-four incurved varieties, and easily secured the chief prize with even blooms, Prince of Wales and Prince Alfred being very well represented. Mr. Warde and Mr. S. Davis, The Cemetery, obtained the other prizes with fairly good blooms. The same exhibitors held similar positions with eighteen blooms. For twelve incurved varieties Frederic Pine, Esq., was first with even and good blooms, among which Prince Alfred, Mr. Brunlees, and Lord Derby were particularly notable. J. P. Franklyn, Esq., Maidstone, and J. B. Green, Esq., Tovil, were accorded equal thirds. Mr. F. Pine staged the only collection of *Anemone* varieties, and was adjudged the first prize; some of the blooms were large and well formed, particularly Gluck, Fleur de Marie, and Marginatum. The same exhibitor was again first with six Japanese blooms, bright and fresh, followed by Mrs. Stoddart Douglas, Tuubridge Wells, and Mr. Warde.

The fine-foliage plants were very useful in filling up what would otherwise have been unpleasantly bare spaces between the *Chrysanthemums*. Three very good collections were contributed, the one for which the premier prize was awarded being from Mr. J. B. Green's garden. The plants were well grown and remarkably healthy, the most noteworthy being *Seaforthia elegans*, *Maranta zebra*, and *Adiantum farleyense*. Mr. H. A. Brassey's specimens were very close to the first in merit, a large example of *Fittonia argyroneura* and *Alocasia metallica* were particularly fine. Mr. F. Pine secured the third position with rather small specimens.

The display of Apples in that portion of the building devoted to the fruit was extraordinary, and it is rare to see at exhibitions such handsome examples as gained the chief prizes. Some good Pears were also shown, but much less numerous, as only two classes were devoted to them. The most important exhibits were in the open class for eighteen dishes of Apples, distinct varieties; H. A. Brassey, Esq., contributing the first prize—a five-guinea silver cup, and R. Leigh, Esq., M.P., the second and third of two guineas and one respectively. There were four collections staged, all possessing more than ordinary merit, but that from W. Skinner, Esq., Broughton, for which the cup was awarded, was unquestionably one of the finest that has ever been staged. Some examples of Loddington were magnificent, and measured 14½ inches in circumference. Warner's King, Beauty of Kent, Mère de Ménage, and Bedfordshire Foundling were also of great size and excellent form. The following varieties, which completed the collection, were admirably represented by clean handsome fruits—Golden Knob, Cox's Orange Pippin, King of the Pippins, Court Pendu Plat, Wyken Pippin, Mannington's Pearmain, Hanwell Souring, Blenheim Pippin (very fine), Winter Hawthornden, Round Winter Nonesuch, Pomeroy, Tower of Glamis, and Ribston Pippin. This handsome collection was greatly admired both by the pomological and general visitors. The second prize was accorded to Mr. H. A. Brassey for excellent Apples, very little inferior to the first; the following varieties being especially well represented by handsome specimens—Cox's Orange Pippin, Brabant Bellefleur, Golden Noble, Small's Admirable, Dutch Mignonne, Beauty of Wilts, and Blenheim Pippin. Sir Francis Geary, Bart., Oxonhoath, was third with large fruits but rather green; a dish of fine New Hawthornden was noteworthy. In the two classes for dessert and culinary Apples respectively, nine dishes of each, W. Robinson, Esq., offered the chief prizes, some fine specimens being staged in competition. Mr. A. Warde had the best collection of dessert varieties, clean and good in form—Keddleston Pippin, Cox's Orange Pippin, Ribston Pippin, Melon Apple, and Golden Russet were very even and handsome. G. Edmett, Esq., had good Ribston and Wyken Pippins in his second-prize collection; L. Killick, Esq., Langley, taking third with fine Worcester Pearmain among others. Mr. Warde obtained a similar position with nine dishes of culinary Apples of good size and even—Hanwell Souring, Mère de Ménage, Belle Dubois, and Loddington were remarkable. Mr. Brassey was a close second, and Mr. Killick obtained third with specimens of Loddington and Warner's King in good form. For three dishes of Apples Mr. Brassey was first in the dessert class with Claygate Pearmain, Blenheim Pippin, and Cox's Orange Pippin beautifully ripened. W. Blest, Esq., Wateringbury, and Mr. Braddick followed with smaller but good specimens, Braddick's Nonpareil in the last-named collection being excellent. A. Killick,

Esq., Weaving, was the most successful exhibitor in the culinary class, easily securing the first prize with handsome examples of Cellini, Blenheim Pippin, and Weaving Apple. Mr. Green was second with nearly equally good fruit. Mr. Braddick taking the third position. Culinary Pears were well shown by G. Stockdale, Esq., Watlingbury, and dessert varieties by Mr. Braddick, these gentlemen securing the premier prize in each class, the latter staging some very good specimens of Chaumontel and Glou Morceau. Mrs. Stoddart Douglas was the principal exhibitor of Grapes, taking first prize in each class with medium-sized bunches of Black Alicante but superbly coloured, and Muscat of Alexandria rather small but apparently well ripened. Other moderately good Grapes were sent by J. Whatman, Esq., Vinters; J. Hollingworth, Esq., Turkey Court; and Capt. Brenchley, East Sutton.

Among the special exhibits the most remarkable was a collection of Apples from Mr. L. Killick, comprising 150 varieties all in good condition, but the Loddington Seedling in the centre were extremely fine. A special prize was deservedly awarded to Mr. Killick. Mr. Braddick sent a basket of handsome Pears; Messrs. Thomas Frost and Sons had collections of Potatoes shown as grown. In the large hall Herbert Monckton, Esq., Maidstone, exhibited a basket of vegetables and fruits which were tastefully arranged with foliage and flowers, the dried silvery pods of Honesty forming a pretty margin. Mr. S. Dean contributed beautiful baskets of Chrysanthemum blooms arranged with foliage over the handle and rising from the centre of the basket into a hemispherical mass of bright and carefully selected colours. This was highly commended by the Judges.

The weather proved as favourable as could be desired, and large numbers of visitors attended the Exhibition, especially in the evening.

SOUTHAMPTON.

The autumn Exhibition of this Society was held in the Victoria Skating Rink on the 16th and 17th inst., the groups of Chrysanthemums and plants completely filling the large building. The cut flower classes were also much better than last year, whilst the fruit and vegetables were most abundant. The whole of the arrangements were most satisfactorily carried out by an energetic executive with Mr. Fuidge as Secretary.

In the nurserymen's class for a group of plants Messrs. Oakley and Watling were awarded the first prize, Messrs. J. and C. Ransom the second, and Mr. E. Hillier the third; all exhibiting small but useful specimens. In the corresponding class for gardeners Mr. Wills, gardener to Mrs. Pearce, The Firs, Bassett, was a very good first; Mr. J. Aymes, gardener to Mrs. Eliot, York, occupied the second position; and Mr. Hinds, gardener to Lord Wimborne, the third. For a group of Chrysanthemums arranged in a limited space there were six competitors, the post of honour being obtained by Mr. Allen, gardener to J. Bailey, Esq., Elmfield Hill, Mr. Wills being placed second, Mr. Aymes third, and Mr. T. Osborne, gardener to J. Buchan, Esq., Wilton House, fourth, all exhibiting well. For twelve and six plants and six Japanese plants grown on single stems there was a spirited competition between Messrs. Wills, Aymes, Allen, Osborne, and Thomas, who secured the principal prizes. The plants exhibited were not trained with that uniformity customary at the London shows, neither could the flowers in all cases be said to be of such excellence, still the majority were very showy and attractive.

In the open class for twenty-four cut blooms, sixteen incurved and eight Japanese, the back row to be Japanese, there were six collections staged, the premier award of the Exhibition going to Mr. Molyneux, gardener to W. H. Myers, Esq., Swanmore Park, Bishop's Waltham, for a collection that we have only seen surpassed this season by Mr. Tunnington at the Kingston Exhibition for the challenge vase. Mr. Molyneux's blooms were large, fresh, and of that beautiful globose form that is so desired in a good incurved flower. Mr. Wills was a very good second, Mr. Moorman third, and Mr. Stillaway, gardener to the Right Hon. Earl Cairns, Bournemouth, fourth. In the other classes Messrs. Molyneux, Wills, and Moorman were the chief prizetakers.

Fruit and vegetables were plentiful; several fine stands of Grapes were staged; the Apples and Pears not only large but highly coloured. Poinsettias, Primulas, and Cyclamens were all well represented. It was, collectively, a very fine show, and combined as it was with an exhibition of British and foreign cage birds, attracted a large number of visitors.

TUNBRIDGE WELLS.

Under most unfavourable circumstances as regards the weather this Society's annual Exhibition of Chrysanthemums, plants, and fruit was opened on Thursday, the 18th inst., in the handsome hall near the station. Snow was falling nearly the whole of the afternoon, consequently deterring a large number of persons from visiting the Show, but fortunately the weather proved remarkably fine on the following day. The display of Chrysanthemums was one of the largest held this year, the specimen plants, particularly the dwarf-trained Pompons, being excellent; but the cut blooms, though numerous and neat, were slightly deficient in size and substance in the majority of the collections. Provision was made for the exhibition of miscellaneous plants, and those for table decoration were very well represented; but the fruit was the chief feature of the Exhibition both in quantity and quality, the Apples being staged in most satisfactory condition. The schedule contained no less than sixty-three classes in three divisions—A, open to all exhibitors in East Kent and

Mid-Sussex; B, for gentlemen's gardeners and amateurs within a radius of fourteen miles of Tunbridge Wells; C, for those within an eight-mile radius of this town; and D, devoted to fruit classes similar to division A. The prizes were not of high amount, the majority ranging between 10s. and 2s., and yet the entries were numerous, as they often are where many small prizes are offered instead of a few large ones. It is scarcely necessary to add that under the superintendence of the Secretary, Mr. E. Charlton, the general arrangements were highly satisfactory.

Among specimen Chrysanthemum plants one of the most important classes was that for a group of eight arranged for effect, the style of training not being stipulated but left to the exhibitor. The chief prize in the class was a silver cup, value three guineas, offered by the tradesmen of Tunbridge Wells, and formed, of course, the coveted object of the competitors, though the second and third prizes were £2 and £1 each respectively—with the exception of one other class the highest offered. There were four entries, the plants constituting bright and effective groups to the left of the entrance, at one side of the spacious and handsome hall which the Society is so fortunate in obtaining. Mr. F. Early, gardener to G. A. Brittain, Esq., Ferndale Park, succeeded in winning the cup with vigorous dwarf and pyramid and standard specimens, both foliage and blooms of which were excellent. They were tastefully and effectively arranged; the most noteworthy varieties being Peter the Great, Magnum Bonum, Dr. Sharpe, Prince of Wales, and Fair Maid of Guernsey, all exceedingly well flowered. The second position was accorded to Mr. Adams, gardener to T. Grant, Esq., for smaller specimens, but indicating similarly good culture. Mr. J. Allan, gardener to Lady G. Field, Ashurst Park, followed with bright and healthy examples, but rather deficient in the number and quality of the blooms. The corresponding class in division B was also for eight specimens, a silver cup of equal value to that already noticed being given by the ladies of the district as a first prize. This, although restricted to fewer growers, was also well competed for, three attractive groups extending nearly half the length of the hall on the right of the entrance, thus corresponding with those in the first class. Mr. J. Wilkins, gardener to Mrs. S. Williams, Shirley Hall, Langton, contributed the best collection, including plants in a surprisingly vigorous state, the foliage excellent and the flowers of good form; Mrs. Sharpe, Fulton, and Mrs. G. Rundle were the most noteworthy. Mr. R. Beilby, gardener to W. H. Tindall, Esq., Hollyshaw, Camden Park, was second with less luxuriant but neat and profusely flowered specimens. The third position was accorded to Mr. J. Nutting, gardener to Col. Ramsden, Ashurst, for rather small plants, among which was, however, an admirable specimen of the bright and effective variety Bob. The entries in the class for six dwarf-trained large-flowered varieties constituted an imposing bank at one end of the hall, serving well to balance the Pompon specimens at the opposite end. The premier award was secured by Mr. Early with well-grown, handsome, and profusely flowered specimens of Prince of Wales, Mrs. Haliburton, Baron Beust, Golden George Glenny, and Mr. G. Rundle, all very even and cleverly trained. Mr. John Charlton, Summer Vale Nursery, was a very close second, the blooms large and of good shape, and the plants vigorous, though the stakes employed in training were slightly too prominent. Mr. Wilkins took the third place with neat and healthy plants, but bearing comparatively few blooms. The Pompons were remarkable for their great size generally and the abundance of their blooms. Those opposite to the incurved were particularly fine, and Mr. John Charlton well deserved the first prize he obtained for six large and handsome specimens, of which President Decaisne, Cedo Nulli, Fanny, Calliope, and Mr. Astie were excellent in every respect. Many other admirable collections were staged, the principal prizetakers being Messrs. Beilby, Early, Mitting, and Wilkins. The total number of specimens exhibited exceeded two hundred—sufficient to occupy considerable space, and in a less commodious building could not have appeared to nearly so much advantage.

Cut blooms were numerous represented, but in many of the collections there was plenty of room for improvement; indeed some were a long way from the exhibition standard. However, those accorded the chief honours in the classes were in several instances marked by more than ordinary merit. The best twenty-four incurved blooms in division A were staged by Mr. J. Allan; they were even, fresh, and moderately good in substance, especially Cannell's Bronze, Rev. J. Dix, Princess of Wales, and Guernsey Nugget. Mr. John Charlton's second-prize blooms were smaller, but neater and very clean. The B class for twenty-four incurved was not very well filled; Mr. A. Henderson, gardener to J. Deacon, Esq., Mabledon Park, taking the chief prize for fairly good blooms, among which Barbara was especially worthy of notice. In the open class for twelve of the same section Mr. Charlton won with medium-sized blooms, but of excellent form. Queen of England, Antonelli, Mrs. G. Rundle, Golden George Glenny, Rev. J. Dix, and Lady Hardinge were the best in the stand. Mr. W. Cornwall, gardener to F. Burchard, Esq., Horsted Place, Uckfield, and Mr. Early followed with fair collections. Mr. J. Charlton was again in the chief position with twelve Japanese, his blooms possessing a creditable freshness and purity of colour. Bismarck, Garnet, Striatum, Mons. Charles Hubert, and Red Gauntlet were also of good size. Mr. Early was in this case a close second, but the varieties were not quite so distinct or well chosen. Mr. Allan was a good third with neat blooms. Japanese were well represented in two other classes. Mr. G. Ware, gardener to Miss Morgan, Hangers-

hill Park, Messrs. Allan and Early, being the prizetakers. Mr. Ware also staged two handsome collections of Anemone Pompons—namely, six and twelve, and obtained the principal prize in each class with fine examples of Calliope, Mr. Astie, Antonius, Madame Montels, Mrs. Wyness, Rose Margaret, and Regulus.

Several classes were devoted to such plants as Primulas, table plants, Epiphyllums, Gesneras, &c., in all of which there were noteworthy specimens; but the most remarkable of all were the plants of *Gesnera zebrina*, for which Mr. D. Buchanan, gardener to Dr. Siemens, Sherwood Park, obtained the first prize. They were in uncommonly vigorous health, the foliage large and richly coloured, while they were flowering most profusely, forming a really handsome group. Some of the Primulas were also well flowered, particularly those from Messrs. Beilby and Henderson. The best six table plants were contributed by Mr. G. Goldsmith, gardener to P. C. Hardwicke, Esq., Tunbridge, who had elegant and useful plants of *Aralia Veitchii*, *Grevillea robusta*, *Dracæna Guiffoylei*, and *Casuarina sumatrana*, all in 6-inch pots and very healthy. Among the not-for-competition exhibits were the following—From Mr. Early, a large and handsome specimen of *Chrysanthemum Peter the Great*, dwarf-trained, more than 4 feet in diameter, and bearing nearly two hundred fine blooms; the training was excellent, and the plant was greatly admired. From Mr. H. Cannell flowers of *Zonal Pelargoniums* and Primulas, very bright and attractive. But the most charming of all the miscellaneous exhibits was a group of *Calanthes* and *Sonerila Hendersoni* from Mr. W. Miles, gardener to D. Harris, Esq., Lamberhurst. The *Calanthes* were flowering very freely, but the chief feature of the group was the *Sonerila*. The plants were of various sizes, but the majority were in 60-size pots and in admirable condition for decorative purposes, the peculiar silvery-spotted foliage and abundant rosy flowers being remarkably handsome. Some handsome specimens of *Poinsettia pulcherrima* major were exhibited by Mr. J. Charlton; they were in 6-inch pots, very compact in habit, branching, and bearing several large heads of bracts, which possessed somewhat of a rosy tinge. This variety is admirable for decorative purposes, as it is surprisingly effective.

Fruit was very abundant and good, about 230 dishes being staged, and the display of Apples and Pears was surprising, a wide table stretching half the length of the hall being entirely occupied with the entries in those classes. For a collection of twelve dishes of fruits only two competitors appeared, the first prize being secured by Mr. Henderson with excellent Grapes, Pears, and Apples. Of the first-named the Black Alicante were notable for their well-finished appearance; while the Beurré Diel and Glon Morceau Pears, with King of the Pippins, Blenheim Pippin, and Cox's Orange Pippin, were of good size and colour. Mr. J. Allan was second with clean well-grown fruits, one bunch of Gros Colman Grapes being well finished and large. The best three bunches of black Grapes were the finely coloured Black Alicantes from Mr. A. Bashford, gardener to Mrs. Stoddard Douglas, Chilston House; Messrs. Allan and Henderson following with smaller bunches and berries. Mr. W. Johnston, gardener to the Marchioness Camden, Bayham Abbey, won the premier prize for white Grapes with three good bunches of well-ripened Muscat of Alexandria. In the class for six dishes of dessert Pears there were six exhibitors, Mr. Goldsmith being placed first with fine fruits of Beurré Diel, Beurré d'Amanlis, Doyenné du Comice, and Conseiller du Cour. For three dishes of culinary Pears Messrs. Johnston and Goldsmith secured the prizes, the first with extremely large examples of Uvedale's St. Germain, Verulam, and Catillac. Mr. Henderson had the best six dishes of dessert Apples, even and well-coloured fruits of Ribston Pippin, Blenheim, and Golden King among others. Messrs. Goldsmith and Allan followed closely. Mr. Henderson held a similar position in the corresponding class for culinary Apples, staging Northern and Yorkshire Greenings in excellent style, Mr. Goldsmith and Mr. K. Maher, gardener to Mrs. Foster, Boyne House, securing the remaining prizes. Of the classes for threes and single dishes it is not necessary to speak in detail, but the majority were excellent.

The whole Exhibition was a very creditable one to the Society, but with additional funds at their command no doubt even better results would be obtained, as many of the prizes might be advantageously increased in value.

RICHMOND.

As an effective and handsome floral display the Exhibition held at Richmond on Tuesday and Wednesday last is entitled to rank among the finest *Chrysanthemum* shows of the season. The spacious and beautiful assembly rooms of the Castle Hotel, in which the numerous exhibits were so tastefully arranged, are admirably adapted to displays of this character, the successful disposition of varied plants and flowers being considerably facilitated by harmonious surroundings. Groups of miscellaneous plants, *Chrysanthemums* predominating, forming fine masses of colour at the sides of the rooms, agreeably relieved by graceful Palms and Ferns, while long tables bore the numerous collections of cut blooms. Fruit was well represented, Apples especially; Pears being shown in fair condition. Vegetables were good, table decorations attractive, and the miscellaneous exhibits both abundant and of excellent quality. Altogether the second autumn Exhibition of the Society was a decided success, and the Committee with their able Secretary, Mr. Albert Chancellor, have reason to be well satisfied with the results of their efforts. The follow-

ing is a necessarily brief review of the principal classes, the short time at our disposal compelling us to curtail the report.

The groups of *Chrysanthemums* formed the chief feature of the display in the larger of the two apartments, eight exhibitors competing. Mr. G. Harding, gardener to J. D. Galpin, Esq., Putney, secured the principal award with healthy vigorous specimens bearing unusually handsome blooms; Mrs. Beckford, Orford House, Ham, and Captain Webb, Riverside, Twickenham, obtaining the second and third places with similarly attractive groups. Mr. E. Beckett, gardener to J. P. Currie, Esq., Sandown House, Esher, staged some good specimen plants, and many other fine collections were contributed. The cut blooms were generally of good substance, clean, well formed, and numerous. The collection of eighteen incurred varieties were excellent; Mr. H. West, gardener to H. Hoskins, Esq., Putney, staging the finest examples; but the class for twelve incurred was by far the strongest, there being a dozen competitors, all exhibiting well. Mr. W. R. Strong, gardener to Mrs. D. Reid, Virginia Water, was an excellent first, closely followed by Mr. J. Hill, gardener to A. Savory, Esq., Chertsey; Mr. West; and Mr. G. Kent, gardener to Lord Brabazon, Coombe End, Kingston. Japanese varieties constituted a grand display, the best collection of twenty-four being from Messrs. Beckett, Strong, and J. W. Moorman, gardener to Miss Christy, Coombe Bank, Kingston, all exhibiting handsome and brightly coloured blooms very close in merit. Twelve Japanese were well shown by Mr. Hill, who also had the finest stand of Anemone varieties.

There were eighteen entries in the class for four dishes of Apples, Mr. W. Fanning, The Convent, Roehampton, and Mr. F. R. Kinghorn taking the chief prizes with fine specimens. Pears were not so numerous nor so good; but collections of fruit and Grapes were well shown by Mr. Hudson, gardener to A. J. Atkinson, Esq., Gunnersbury House, and Mr. W. Bates, gardener to J. E. Meek, Esq., Poulett Lodge, Twickenham. The competition for the special prizes was generally good, and the miscellaneous exhibits numerous.

During the afternoon of the opening day a large and aristocratic company assembled; H.R.H. Princess Mary also honouring the Society by visiting the Exhibition.

THE usual monthly dinner of the HORTICULTURAL CLUB took place at the Club House, Arundel Street, Strand, on Tuesday, the 16th. There was a large attendance of members. The following have recently been elected members:—Thomas B. Heywood, Esq., Reigate; J. Adams, Esq., Tavistock Street; C. F. Hore, Esq., Holden, Beckenham; and E. Badger, Esq., Birmingham.

— A CORRESPONDENT sends us the following note—"The recently formed FINSBURY PARK AND DISTRICT AMATEUR CHRYSANTHEMUM SOCIETY held its first annual Exhibition at the Holloway Hall on 16th and 17th inst. The Society has begun in a small way, but there is every reason to believe that it will develop and increase largely in importance in the course of a few seasons. As it is, the Show reflected great credit upon the Committee and the indefatigable Honorary Secretary. The exhibits were arranged in the small hall; but if the Society meet with the encouragement and support it deserves and the Committee anticipate, the large hall may possibly be utilised in future years. In several instances the plants were very fine, and the cut flowers contributed by Mr. Cochrane, Superintendent of Finsbury Park, were also well worthy of notice. The effective decorations of the hall were supplied from the establishment of Messrs. Cutbush and Son of Highgate; and Mr. Howes of Blackstock Road, nurseryman, exhibited some plants, but they were not for competition. Messrs. Rundell, Charlett, and Boyd were the chief prizetakers."

— THE cut flowers of *SALVIAS* staged by Mr. H. Cannell of Swanley at the Royal Horticultural Society's last meeting, and at the Royal Aquarium on the following day, attracted the attention of many visitors, who were apparently unacquainted with the beauty of some species and varieties at this dull season. But if a few flowers were sufficient to awaken so much admiration, it can readily be imagined that a house 100 feet long full of *Salvias* of such brilliantly-coloured forms as *Piteheri*, *splendens* *Bruanti*,

Betheli, pseudo-coccinea, and Hoveyi, must be simply unique. Yet at Swanley there is a house of the dimensions named devoted entirely to these charming plants, all in pots, vigorous, and profusely flowered. The first three, for which certificates were awarded at Kensington, cannot be too strongly recommended.

— LIKE many of its allies, such as the *Melastomas*, the *Bertolonias*, and the *Lasiandras*, we have in the *SONERILAS* charming plants for decorative purposes, some combining pretty flowers with a corresponding attractiveness of foliage, the latter being by far the most durable portion of the plant's beauty, as the flowers in many are rather fleeting. There are several species and varieties of *Sonerila* in cultivation, but none can surpass *S. Hendersoni* when in such fine condition as it was shown by Mr. Miles at the recent Tunbridge Wells Exhibition. Some of the plants were in 48 and 32-sized pots, forming bushy profusely flowered specimens, but the majority were in 60-size pots, neat, little, extremely useful plants. The peculiarly silvery mottled and spotted leaves constituted a natural and admirable background to the abundant clusters of rosy-tinted flowers, and rendered the collection in which they were included the admiration of all the visitors. Other and similarly attractive forms are *S. margaritacea* and *S. picturata* that differ from the one noted above in the colour and markings of their foliage.

— ANOTHER feature at the same Exhibition was the plants of *GESNERA ZEBRINA* sent by Dr. Siemens' gardener, Mr. D. Buchanan, and for which the first prize was awarded in the class. These well indicated the great decorative value of a generally appreciated plant that is, however, rarely seen in such perfection. Mr. Buchanan has evidently given it exactly the treatment it requires, for more compact specimens, with more richly-coloured foliage and a greater profusion of bloom in 48 and 32-sized pots, it would be difficult to obtain. *Gesnera zebрина* is unquestionably one of the most useful of the genus, for it succeeds under cooler treatment than the majority, producing its brilliant flowers freely at a time of year when it is not easy to maintain an effective floral display. But were the deeply coloured foliage its only recommendation it would still amply repay the grower for the moderate care needed to have it in satisfactory condition.

— THERE was still another group at Tunbridge deserving of note—namely, the plants of *POINSETTIA PULCHERRIMA MAJOR* contributed by Mr. John Charlton of the Summer Vale Nurseries. This variety of a plant that is too well known and valued to require comment, differs chiefly from the type in its compact branching habit, the larger heads of bracts, and the tinge of crimson which pervades the latter. This difference of hue is very noticeable when the plants are in a bright light. The specimens sent by Mr. Charlton were also remarkable for the comparatively small pots they were in, none exceeding 6 inches in diameter, and yet the plants were as compact and healthy as could be desired. A few dozens such plants would prove of inestimable value in many gardens during November and December.

— THE EXHIBITION OF CHRYSANTHEMUMS IN FINSBURY PARK still continues, and the blooms have considerably improved in size and quality. The Show being open on Sundays is visited by numbers of persons, and from the many varieties represented it affords intending growers a good opportunity of making a selection.

— IN connection with the INTERNATIONAL HORTICULTURAL EXHIBITION proposed to take place at Manchester in 1881, a meeting was held in the Town Hall of that city on the 16th inst., the Mayor presiding. Mr. Bruce Findlay said he had received a telegram from Sir Henry Ponsonby, at Balmoral, stating that Her Majesty the Queen would patronise the proposed International Exhibition in the same manner as in 1873. The subscriptions

promised up to date were as follow:—Her Majesty the Queen, £25; Lord Derby, £100; General Horticultural Company (Limited), 100 guineas in special prizes; Lord Egerton, Lord Wilton, Sir Humphrey de Trafford, and Mr. John Rylands, £50 each; the Duke of Devonshire, Earl of Stamford and Warrington, and Mr. Joseph Broome, £25 each; Mr. Hugh Mason, M.P., £20; the Trustees of the late Duke of Bridgewater, £20; and smaller subscriptions amounting to £200, making a total of £800, which was increased to about £1000 before the close of the meeting. A resolution was passed requesting the Mayor to accept the chairmanship of the General Committee, to which he consented. An Executive Committee was appointed, and a resolution was passed to appeal to the residents of Manchester for the necessary subscriptions, and that any balance shall be applied to rebuilding the glass houses at the Botanic Gardens, Old Trafford.

— A CORRESPONDENT writes to us as follows on the FROST IN LANCASHIRE:—"Winter appears to have set-in in this county in a decided manner. For several nights the mercury of the thermometer has fallen from 10° to 14° below the freezing point, and has only risen a few degrees during the day. The ground is covered with snow to the depth of 3 or 4 inches, and the trees glitter with innumerable crystals, fogs having prevailed during the frost with but little sun. All ordinary gardening operations are suspended."

— "A VISITOR" describes Mrs. Heywood's large CONSERVATORY AT NORRIS GREEN, near Liverpool, as a "blaze of beauty." Even the Chrysanthemums, effective as they are, are quite eclipsed in brilliancy by the Zonal Pelargoniums *Vesuvius*, *Wonderful*, and some others of various sizes that are flowering as profusely as in summer, and promise to continue for an indefinite period. These, with *Celosias*, *Primulas*, *Roman Hyacinths*, *Erieas*, *Cyclamens*, *Mignonette*, *Cannas*, *Solanums*, and others, with a margin of *Isolepis*, produce a beautiful display. The many hundreds of flowers are seen to the greater advantage in contrast with the splendid specimen *Camellias* that occupy the central borders, and are in superb condition both as regards the healthiness of the foliage and the number of buds.

— A PLANT, or rather small tree, of *LUCULIA GRATISSIMA* in the structure demands special mention. This was planted about four years ago in the conservatory border, and allowed to follow its natural habit. It is now covered with numerous trusses of flowers, some of them nearly a foot in diameter. These have been produced continuously since September, and the plant will remain a striking feature of the structure, which it fills with fragrance, for some weeks to come. The condition of the plants and the arrangement are sufficient evidence of Mr. Bardney's skill and good taste.

— ONE of the finest green Hollies that can be grown in suburban, or, indeed, in any gardens, is *ILEX HODGINSII*. We have recently been inspecting the shrubs in a garden where smoke and sulphurous vapours prevail, and no varieties of Holly can exist except the one named, which grows with the greatest freedom, its large glossy leaves shining conspicuously amongst many other shrubs that are dead or dying in the borders. This fine Holly ought to be largely grown in smoky districts.

ANTHURIUM ANDREANUM.

THIS handsome plant has received considerable attention during the last few months, and we have had so many inquiries respecting it that the accompanying woodcut, for which we are indebted to the General Horticultural Company, will no doubt be welcomed by those who have not had an opportunity of seeing the plant itself. The engraving well indicates the general character of the plant, and scarcely needs any description, except in stating that the colour of the large strangely corrugated spathe is a most brilliant scarlet, the surface being smooth and shining. Like the useful and attractive *Anthurium Schertzerianum* this species is

not of difficult culture, but the plants must attain a moderate size before they will produce large and satisfactory spathes.

It is a native of New Grenada, where M. André found it growing both upon the branches of trees, particularly on *Ficus elastica*, and also in moist positions on the ground. Specimens were forwarded to M. Linden of Ghent, who subsequently exhibited it both in Belgium and England. The first plant shown in this country was submitted to the attention of the Royal Horticultural

Society's Floral Committee in April of the present year, when it was greatly admired, a first-class certificate being at once accorded for it.

THE MAGNUM BONUM POTATO AND ITS RAISER.

No Potatoe during recent years have obtained such widespread popularity as the Champion and Magnum Bonum. Their great

Fig. 86.—ANTHURIUM ANDREANUM.

vigour has enabled them to resist the disease that has been so prevalent during the past inclement seasons in a remarkable manner. These varieties have not only attracted much attention in different ways and from various causes, but they have proved of real usefulness; for in not a few instances, when all other varieties succumbed to the murrain, these remained practically unscathed, and afforded valuable and, in many cases, excellent

food. An historical reference to one Potato and its raiser having been given on pages 440 and 441, we now give the same prominence to the other. The following letter, written by the raiser of the Magnum Bonum, tells the story of a life that will not be uninteresting, and the history of a Potato that has proved its worth both for exhibition and culinary purposes:—

“I was born at Tuckton, a village about a mile to the west of

Christchurch in Hampshire, on the 1st of May, 1825. My father was a farm labourer. At the age of nine years I was sent to work on a farm in the neighbouring village of Iford, at 1s. 6d. per week. I had had but little education, and had never taken a pen in my hand. When I was twelve years of age my parents moved to the east end of Christchurch, and I then went into the service of a medical man to look after his pony and to work in the garden. After this my father, who liked gardening, was taken on as an under gardener at Sir George Rose's, Sandhills, Mudeford, and I went into the employ of Mr. Wm. Orchard, a market gardener at Christchurch. Although the wages were

small I remember with thankfulness the kindness I received from this good old man and his wife. I worked for Mr. Orchard for two years, and then obtained employment at a cornfactor's in the town, a Mr. Charles Hicks, and he being fond of his garden, and seeing that I took an interest in keeping it in order, we got on very well together. I was ten years in this place.

"In June, 1855, I went as gardener to Mr. J. Sopp, a gentleman who had a large boarding-school at Christchurch. It was there that I had my first experience with seedling Potatoes. The first season I found a root of seedlings, self-sown, amongst the crops in the garden, with thirteen tubers; I took care of them, and was

Fig. 87.—MR. JAMES CLARK.

much interested in the variety there was in the produce of this one root. One of them proved a very early round white, and I grew it for several years, but it became so subject to disease that I was obliged to discontinue growing it. While in this situation my health gave way, and I was compelled to give up the place. When I was able I went to the jobbing work, taking up pruning and the lighter parts of the work. In 1869 I removed from Christchurch to Cranemoor, where my wife undertook the care of a small chapel. In return for this we were allowed a cottage and three-quarters of an acre of land rent free. I employed the land in growing garden produce for market, and as the soil was rather stiff I grew Roses for sale, that being a work I was fond of, and one which I thought would pay. In June, 1870, I was again laid

aside with heart disease, and was so thoroughly broken down that I was told I should not be able to take any active part in life again. In the spring of 1869 I had bought 1 lb. of Early Rose Potatoes; these I cut into fifty sets, and let a neighbour have half, and planted the other half myself. The sets planted in my own garden produced 30 lbs. These I had taken to Cranemoor with me, and planted in the spring of 1870. In the month of July, in my weak state, I lifted these Early Rose a few roots at a time as best I could. It took me many days to get them all up, but the weather was very bright and dry. One day as I was quietly walking by the spot where these Potatoes had grown I picked up four little seed balls with the thought that, if spared, I might get some good sorts of Potatoes from them. The seed

was sown in April, 1871, and I had forty-two roots of seedlings, with no two roots alike, and all differing from the parent in some way or other. What the male parent was I cannot tell, as I had many sorts planted, and there were allotment gardens close by with many other varieties planted in them. I have never seen any other seed balls on Early Rose since except from blooms I have crossed myself, and from these I have not found so much variety as from those above mentioned.

"The next spring some kind friends helped to have my ground dug and planted, and as I continued weak and unable to exert myself in any way it gave me much pleasure to mark the progress and variety of these seedlings. As the season advanced the disease attacked the whole crop of Potatoes, and the haulm of all kinds went off very quickly. Not a green leaf was to be seen in field or garden except on one of my seedlings. One day a friend was walking through the garden with me, and coming to the seedlings, and seeing the green haulm, asked what Potato it was. I told him it was a seedling, and quite distinct from all other Potatoes that I knew. In 1873 it made its mark yet more distinctly, and I had rather more than a bushel of seed. When I dug them I told a brother gardener that I thought it was a Potato which in a few years' time would take a leading place in the market.

"In the spring of 1874 I discarded many of my seedlings as worthless, but found the one referred to and a few others very promising, and from these I selected six sorts, and sent them to Mr. Shirley Hibberd for trial. Mr. Hibberd wrote to say in reply that it was not his practice to take seedlings for trial, and I was not to be surprised if I heard no more of my seedlings. In the autumn, however, I received a note from Mr. Hibberd saying that he liked some of them well, and that if I wanted to sell the stock he thought he could find me a customer; at the same time he advised Messrs. Sutton of Reading to apply for the stock. In response to a note from them I took some samples to Reading, when Mr. Martin J. Sutton selected Nos. 2 and 7, and bought the stock from me. No. 7 was the seedling which from the first withstood the disease in such a marked manner, and it is now known as 'Suttons' Magnum Bonum,' a name given it by the Reading firm, to whom I sold not only the entire stock dug that year, but the right to call the Potato whatever they liked.—JAMES CLARK."

Such is the history of the Magnum Bonum and its raiser, and we trust that Mr. Clark, and the raiser of the Champion, Mr. Nicolls, will live long in the esteem of the many whom they have benefited by having been the means of supplying them with Potatoes when otherwise they would have had none. They have done what many others have done with great results—namely, made the best of small means, and have turned what numbers of people would have regarded as trivial circumstances, almost accidents, to excellent account.

MORE ABOUT BLACKBIRDS.

I AM very grateful for the accurate and specific information as to the colour of the bill of the blackbird so kindly contributed through the columns of the Journal by such authorities as Mr. Harrison Weir and Mr. Hiam.

Birds appear plentiful this season, and already, before this bitter snowy weather succeeded two or three days of exceptionally high temperature and strong sunshine, they seemed pressed for food, coming close to the house and to the window sills. Being often a prisoner in winter, my powers of observation are but limited, but I had been interested a short time back in noticing some blackbirds amongst some Rose bushes which had been protected with the usual top-dressing for the winter, and after grubbing about on the ground one or two actually perched on the standards. The following number of the Journal (Nov. 1st) contained on page 435 Mr. Hiam's interesting "Notes on Birds," and there I found described what doubtless had been the attraction to the blackbirds here, as to those which visited Mr. Hiam's Pear tree. As far as I could see none of these birds had yellow bills; but a day or two later they came again, and my attention was directed to a pert handsome bird flapping on a Privet hedge close by. He must have been a male fully developed, the bill being of a deep but most vivid golden yellow.—A. M. B.

THE METEOROLOGICAL SOCIETY.—The opening meeting of the session was held on Wednesday evening the 17th inst., at the Institution of Civil Engineers, Mr. G. J. Symons, F.R.S., President, in the chair. The following gentlemen were elected Fellows:—G. Corden, E. T. Dowson, F. Hepburn, B.A.; C. M. Hepworth, J. Mulvany, M.D., R.N.; T. H. G. Newton, Captain M. Parry, E. P. Phillips, and H. L. Roth. The papers read were—

1, "Table of Relative Humidity," by Edward E. Dymond, F.M.S. 2, "Rainfall in South Africa," by John G. Gamble, M.A., M.I.C.E., F.M.S. The author gives the monthly total rainfall from 103 stations for the thirteen months, December 1878 to December 1879, and also the monthly means from all stations in South Africa from which a record of five years upwards could be obtained. It is shown that the Cape Peninsula, the south-west and the west coast have winter rains with a dry summer, characteristics of what is called the subtropical region, the rains coming with the N.W. wind or anti-trade; while Natal, Aliwal North, and in a less degree Queenstown, have the tropical features of a wet summer and dry winter. On the south coast the rainfall appears to be more equally distributed throughout the year, though there seems to be an October maximum at Port Elizabeth and Uitenhage. In the central and northern Karroo the maximum of the very scanty rainfall occurs in February and March. These rains generally fall in thunderstorms. Each storm seems to come from a westerly direction, but it is a more or less well-ascertained fact that these rains do not fall up country until the south-easters have set in on the south and south-west coasts. In the south-east of the Colony the transition toward tropical features may be noticed, both Grahamstown and Kingwilliamstown showing a winter minimum in June. 3, "On the Meteorology of Mackay, Queensland," by Henry L. Roth. 4, "Thermometrical Observations on Board Ship," by Captain W. T. Caborne, F.M.S.

NERIUM OLEANDER.

I WAS very much interested by the remarks contained in the extract from the letter of Mr. F. W. Burbidge, Curator of the Trinity College Botanic Gardens, Dublin, sent to your correspondent "W. J. M.," on the culture of this beautiful plant in Paris. I also have often wondered why our nurserymen do not send out flowering plants in small pots as are seen in Paris, for I find the culture very easy. I always grow them in this way, and am able to raise flowering plants from 9 inches to 1 foot high even in 3-inch pots. The stock plants are allowed to grow in the open air during the summer months and ripen the wood on which the flower buds are formed. At the approach of cold weather they are brought into a vinery. In March, when the blossom buds are formed and beginning to swell, cuttings about 6 inches long are taken and inserted in bottles of water, which are plunged into cocoa-nut fibre in a stove having a bottom heat of from 80° to 85°. These cuttings produce roots very rapidly, and when these are about 1 inch long the cuttings are removed from the water and planted in the fibre. In about ten days or a fortnight they can be lifted, and the plants, with the mass of roots and fibre adhering to them, placed in 3 or 5-inch pots and again plunged into the fibre. If treated in this way the plants do not receive the slightest check from the time they leave the parent until they bloom, and when the roots fill the pots the blooms are fully expanded, and the plants can then be removed from the hotbed. In this way I have succeeded in flowering them in six to eight weeks.—THOMAS WM. COWAN, *Horsham*.

TRANSPLANTING GOOSEBERRY BUSHES.

THE timely remarks under the above heading on page 431 would be read with interest by many readers besides myself. Having a square of Gooseberry and Currant bushes in good health, covered-in with inch-mesh wire netting, a few remarks on this subject might not be out of place in the Journal. On taking charge of these gardens five years ago I at once formed a new square of young Gooseberry bushes, not liking them scattered along the sides of the walks all over the garden. Last winter they were covered-in, as the order is "Kill no birds and destroy no eggs;" so we had no Gooseberries worth speaking of till this year. The netting is supported by iron uprights, angle iron running around and across the square, bolted to the uprights—rather an expensive mode of protection, but one that will last for many years. The netting is 5 feet high, with one width sunk 3 inches in the soil around the square. We have, then, a piece of square mesh fish net to hang from the top down over the lower width of netting; this makes all secure, and by lifting the net we can enter at any point. When not needed to protect either fruit or buds the fish net is taken down and stored in a dry place. I have heard that wire netting is injurious, but my bushes have thriven exceedingly well, and retained their foliage to the last.

Caterpillars were rather troublesome at times through the season. I have found the best plan is to dust the bushes with soot and lime, or dry wood ashes mixed with either of the two. As soon as the caterpillars are touched with the mixture they drop off the branches. I do not know if they die then, but so long as I can

keep my bushes free from them in that way I shall try neither hellebore powder nor fir-tree oil. My employer told me he would rather eat a little soot or lime than risk the effects hellebore powder might produce. Another year I shall not wait for the caterpillars to make their appearance, but shall employ both soot and lime freely.

No doubt Mr. Taylor's mode of making new plantations will be found a very useful practice for those who have time and money at their disposal; but where planted as I have described other means must be found to keep them in health for many years. Large Gooseberry bushes mean a quantity of fruit, though it may be not quite so large as that on younger trees. Not one mile from here I noticed some fine Gooseberry and Currant bushes quite leafless, and the Gooseberries were only just changing colour. What will be the condition of these bushes next season?—A. J. S.

THE RECENT INTERNATIONAL POTATO EXHIBITION.

In a circular issued with his Potato catalogue Mr. William Ker of Dumfries states, in reference to the awards at the above Show, "In the class for twenty-four varieties the allocating of the first prize gave great dissatisfaction. Mr. Ker's lot were considered decidedly the best, but were disqualified on account of there being two dishes very much alike, while in reality they were quite distinct." Now Mr. Ker's collection was not disqualified, and no one knew this better than himself! One of the Judges stated to him in the presence of Mr. McKinlay that the collection was considered by them decidedly inferior to the six collections awarded prizes in the class, and the question of disqualification was never raised. It is not a little remarkable that a paragraph appeared in the *Bury St. Edmunds Free Press* a few weeks ago stating that the first prize in the leading class was awarded to Mr. Ellington of Bury St. Edmunds, who was awarded and received the second prize only.—ONE WHO KNOWS.

PLUMS FOR SUCCESSION.

BUT for Plums we should have often had a great difficulty in making up a dessert for a large party within the last two or three years. Good Pears have been few, and those few persisted in ripening one at a time, or else at a season when there was little use for them. Apples are voted common, although I am sorry to say they are far from common in reality; and as for Peaches and Apricots, why the very trees refused to exist. This season the growth is exceptionally good as far as the last two fruits are concerned, and we may reasonably hope, if the frost comes in winter instead of in spring or summer, to see once more some fruit on our south walls. Plums are never absent. Once only within the last ten years has the crop been a thin one, and even then some of the trees bore a full crop. I do not know that there is anything particular in my mode of culture, and think rather it must be that the soil and climate suit Plums, for trees of all ages between five years and forty alike bring excellent produce, and are always worth showing to visitors during the autumn season if we have nothing else to show. Standard Plums are hardly worth taking into consideration now in this locality with the exception of Damsons and Winesours, and these in some seasons cannot be saved from the birds. I much regret this, for Winesour especially is invaluable for preserving, and we must endeavour to grow it against walls in the same way as we are now obliged to grow the Kentish Cherry. I doubt, however, if trained trees of the Winesour are to be had, and I do not think this high-flavoured little Plum is known to everybody. It ripens about the same time as the Damson or a few days earlier, and I imagine would do well under exactly the same conditions. It has no equal for cooking or preserving.

The season during which Plums may be had in abundance lasts from the middle of July to the middle of November; and if good quality is studied we cannot do better than begin with Early Favourite and Early Rivers (syn. Rivers' Early Prolific) and end with Golden Drop and Late Rivers. Blue Impératrice and Ickworth Impératrice are fairly good as late Plums, but I am inclined to think that Late Rivers surpasses them. Reine Claude de Bavay is a most delicious October Plum, being in fact a large October Green Gage; but as I have only one tree of it in bearing, I have not proved its keeping capabilities. Washington on an east wall here follows closely on the heels of Mr. Rivers' two early seedlings above named, indeed I have only one other variety earlier than it, and which I think is Early Blue. Washington is the handsomest of all the Plums grown here, and is quite of good dessert quality; true, it does not always fruit as freely when trained to a wall as some varieties, but it generally has a fair crop,

and is altogether a different Plum to what it is grown as a standard. It is followed by the Green Gage, which is largely grown for cooking and preserving. The season during which the Green Gage is at its best is very short, and if it is allowed to hang on the tree, as many other Plums will after they are ripe, it becomes insipid. I therefore find it best to look them over about every other day, and gather as many as are wanted for dessert just as they become soft. The later-ripened fruits are always comparatively tasteless, and are not equal to Jefferson or Kirke's, which makes a good succession. Then we have the White Magnum Bonum or Egg Plum, which is highly esteemed for all purposes here including dessert; certainly it is not equal to Jefferson in flavour, but its beautiful appearance will always tempt anyone who is not a connoisseur, and most people are satisfied with it when they eat it. It is, however, as a culinary fruit that it particularly excels, being quite transparent when cooked and of a beautiful colour. Like the Green Gage it soon loses flavour after it is fully ripe; but some of the earlier fruit of Golden Drop is ripe by this time, and is more than a worthy successor to it. The season of Golden Drop, which is the most useful of all Plums for a private establishment, is a long one. Some fruits of it were ripe early in September, and there are now (November 18th) sufficient for a dish or two on the trees as well as in the fruit room, and the flavour is, or at least was a few days ago, as good as ever. The varieties I have named form a good succession. There are several other good Plums grown here, and there are also good ones which we do not possess in a bearing state. Among the former are Impériale de Milan, of excellent flavour and very beautiful appearance; Guthrie's Late Green, a useful successor to the Green Gage and sometimes nearly equal to it; Victoria, which never fails to produce crops in any position; and Cooper's Large.

Some of the varieties do fairly well on a north wall, where, though they do not always ripen their fruit sufficiently for dessert, it is always useful for kitchen purposes, and sometimes it will come in at a fortunate time to prevent a scarcity. The best of the varieties I have proved for this purpose are White Magnum Bonum, Golden Drop, Victoria, and Orleans.—WM. TAYLOR.

DIPLADENIA AMABILIS.

I WISH to say a few words in favour of this beautiful stove climber. I grew a small plant in a pot in ainery, which suited it very well till the Grapes commenced colouring and the ventilation was increased. At the end of a pit in a house in which I grew Melons I then enclosed a space 2 feet 6 inches long, 2 feet 4 inches wide, and 2 feet 4 inches deep, including 1 foot of drainage, and planted out the Dipladenia in good soil in March, 1877. It soon commenced flowering, and produced between three and four hundred flowers that season, making strong shoots as well. The next year, still improving, it produced 1388 flowers, and during 1879 it afforded 1811 flowers, often having as many as two hundred flowers open at once. The plant at first shared the roof with a Stephanotis, which I removed last winter, and the Dipladenia now occupies the whole of the space. The wire trellis to which it is trained is 15 feet long by 9 feet wide, and is 9 inches from the glass. Last winter being so very severe injured many of the young shoots, and some were damaged by being so much entwined. In consequence flowering did not commence till May this year, but since then the plant has never ceased producing flowers. Every day during October from 100 to 130 flowers were open together, lasting from ten to fourteen days, and now (November 14th) there are in a temperature of 50° over eighty fully expanded blooms.

My object in writing is to induce others to try it planted out. Anyone having a house in which a temperature of 45° to 50° can be maintained during the night, with a rise to 60° by day, may grow it satisfactorily. I am aware this is a much lower temperature than is generally considered necessary, but from four seasons' trial I find it quite sufficient, the flowers lasting longer during cold weather than when exposed to bright sun. No fire heat was employed during June, July, and August, the house being kept close. The Dipladenia is singularly free from insects; I have never seen green or black aphides, thrips, or scale attack it, only red spider in summer when the plant could not be syringed. Mealy bug I have not been troubled with for some years.—J. T. CREED, *Gardener to T. Swanwick, Esq., Whittington House, near Chesterfield.*

THE INCREASE OF APHIDES.—Naturalists tell us that so very rapidly can the aphides family, or plant lice class of insects, propagate themselves under favourable circumstances, that nine generations may be propagated in three months, amounting to a total of 100,000,000,000,000. To form some idea of what this

bewildering sum really means, let us suppose it possible to place them in a line and at the rate of 100 to the inch, or about 400 to the breath of one's hand. The sun is about 92,000,000 of miles from here, and this supposed line would reach it over 160 times. A man's thumb may cover a square inch, and let us suppose it covers 10,000 of these minute insects, the produce of one of which in one season might be so very great as to cover an area of 1,594,225 acres.—(*The Journal of Forestry.*)

HARDY FRUIT GARDEN.

TAKE advantage of favourable weather to push forward pruning, nailing, and tying-in wall trees; also finish planting as far as practicable. In pruning old trees, especially Apricot, Pear, and Plum trees, overgrown old and barren spurs should be gradually cut back alternately, doing a portion one year and another the next, the object being to keep the fruitful buds as close to the stems and wall as possible. The spurs so cut back will, if the tree is in good health, break at the base, and with proper attention to stopping the growths furnish buds for future bearing. It is, however, always advisable to retain if possible a portion of young wood, and so make sure of growths, as when the spurs are old they do not break freely. Apples and Pears, whether grown as espaliers, bushes, or pyramids, may be pruned with advantage, staking and tying as necessary. To make handsome and fruitful trees pyramids and bushes should be moderately thinned annually, as when hard stopping is practised during the summer the wood is apt to become crowded so much as to seriously affect the ripening of the wood, the production of fruit, and the proper maturation of the fruit if produced. Excessive thinning is not advised, as it would cause the production of useless shoots in the following season; but examining the trees annually and operating so as to prevent them becoming thickets will keep them in good order without being compelled to resort to a severe thinning, as would be necessitated by neglect for a number of years. When the pruning is completed remove the loose inert soil from about the roots and apply some fresh compost, of which a fourth may be thoroughly decomposed manure. Raspberries should now be pruned and tied, leaving about four of the strongest canes to each stool, and after tying them stop at from 4 to 5 feet height, according to the vigour of the canes or height of the stakes or trellis. Apply a good dressing of manure, merely pointing it in about the stools, but in the spaces between the rows and stools it may be buried deeper, being careful to avoid injuring the roots. Proceed with the pruning of Gooseberries and Currants, spurring the side shoots in to about three-quarters of an inch, and thinning-out where too crowded, encouraging young growths. Where Gooseberries grow freely and fruit sparingly, instead of cutting back the side shoots thin them moderately, especially such as cross each other, and this will probably result in a full crop of fruit. Black Currants should only have the old growths removed, encouraging the young shoots, which afford by far the finest fruit. If any fruit trees be infested with moss or lichen dust them thoroughly after rain with fresh-slaked lime, which will also render the buds distasteful to small birds. Bullfinches should be shot. Peach and Nectarine trees may, as soon as the leaves have fallen, be carefully untied from the walls so as to retard their flowering. Thinning the growths or removing bearing wood of the past season may also now be performed, as well as shortening any shoots necessary to originate growths for furnishing the trees. This pruning is not usually performed at this season, but is advisable, as it tends to strengthen the buds for the next crop.

FRUIT HOUSES.

Peaches and Nectarines.—Employ heat in the earliest house only to prevent the temperature from falling below 35° in the morning, but turn on the heat so as to secure a day temperature of 40° to 45° and 50° in mild weather. Ventilate freely above 50°, damping the trees and other available surfaces twice a day—in the morning and early

in the afternoon. If a bed or ridge of fermenting materials composed of three parts leaves to one of stable manure be formed inside the house it will induce the free swelling of the buds, and if turned over and fresh material added occasionally an atmosphere will be afforded highly beneficial to the trees and inimical to insects. Ventilate freely when possible, and close early in the afternoon so as to lessen the necessity for artificial heat, allowing the trees to advance gradually. Ascertain that the border is thoroughly moistened with tepid water, and in the case of old trees with weak liquid manure of the same temperature. The house where the trees are intended to be started early in the year should be cool, ventilating when the weather is mild; but in frosty weather the house may be closed, except when bright, as to keep the house shut during bright days would cause the temperature to rise excessively. Attend to the pruning and dressing of the trees in late houses, and have the houses thoroughly cleaned.

Strawberries in Pots.—A batch of plants may now be started to afford ripe fruit in late February or early March. Early free-setting and swelling varieties should be chosen, such as Pioneer, Vicomtesse Hericart de Thury, and La Grosse Sucrée, the plants being those that were layered and potted early and have formed well-developed crowns, in 5 or 6-inch pots. The drainage should be examined, and if defective rectified, decayed leaves being removed and the surface soil also, but not disturbing the roots, and giving each plant as much bone meal as can be held between the thumb and forefinger, afterwards mulching the surface of the soil with some fresh horse droppings, which will encourage the emission of rootlets. Press it down moderately firm, leaving sufficient space for watering. The pots should have the sides freed of any accumulation of moss or dirt. Place the pots on shelves not more distant from the glass than 2 feet in a house with a temperature of 40° to 45° at night and 50° in the day artificially, above which ventilate freely. The pots need not be on turves or in troughs or saucers, as the plants afford equally good results without, provided due attention is given to watering and the supply of liquid manure after the fruit is swelling. Examine the plants frequently to see that none lack water, and when required supply it liberally. Where there is no house devoted solely to forcing Strawberries they may be accommodated on shelves in an early vinery or Peach house, having the plants near the ventilators.

FLOWER GARDEN.

Roses.—Where it is intended to make new plantations preparation should be commenced at once by having the ground trenched to a depth of 2 feet, and a liberal quantity of manure incorporated. Place the manure in alternate layers with the soil, say a good layer of rather fresh manure at the bottom of the trench, then 4 inches of soil, 2 inches of manure, soil again, and so on. If the soil be light it will be greatly improved by a dressing of clay during the trenching. The clay is very retentive of moisture, and Roses are very partial to it. For stiff soils Roses on the Briar stock succeed admirably, but on light soils they are short-lived and unsatisfactory. Light warm soils may advantageously (and for beds especially) be planted with Roses on their own roots. Varieties that succeed in that way and make effective groups are *Senateur Vaisse*, *Prince Camille de Rohan*, *John Hopper*, *Général Jacqueminot*, *François Michelin*, *La France*, *Dupuy Jamain*, *Etienne Levet*, *Duchess of Edinburgh*, *Comtesse d'Oxford*, *Charles Lefebvre*, *Madame Roland*, *Maréchal Vaillant*, *Marquise de Castellane*, *Baronne de Maynard*, *Capitaine Christy*, *Baronne de Rothschild*, *Madame Lacharme*, *Princess Beatrice*, *Thomas Mills*, and *Thomas Methven*. Roses on the *Manetti* stock also succeed on light soils if well mulched during growth. Roses that are not thriving satisfactorily should be lifted and the ground trenched and well manured. If they have been long in the same position add some fresh soil, and after trimming in any straggling roots replant carefully, spreading out the roots, making the soil firm, and mulching with long manure for the winter. The growths must be well thinned out and cut moderately hard back in spring.

The leaves of deciduous trees and shrubs having fallen shrubbery borders should be cleaned, and where pointing them over without injury to the roots can be performed it may be practised, which will have an invigorating tendency, but where the roots are near the surface a top-dressing of thoroughly reduced material from the

rubbish heap will be beneficial. The spaces between shrubs should be occupied with low-growing spring-flowering bulbous and herbaceous plants. Tender plants will usually winter safely if they are afforded a good mulching over the roots, 4 to 6 inches depth of cocoa-nut fibre refuse being very effectual.

Herbaceous borders requiring re-arrangement should be attended to at once, weather permitting, taking advantage of the opportunity to give the ground a liberal dressing of enriching material, and to turn it over to as great a depth as the good soil admits. If after transplanting or re-arrangement a mulching is given of cocoa-nut fibre refuse it will tend to their better re-establishment. Clear away all dead stems, &c., renew pegs and labels as required, afford a dressing of some enriching substance, and neatly fork over the borders.

PLANT HOUSES.

Greenhouse.—Undue excitement at this time of year is often a cause of the buds of Camellias falling. The necessity of fires to expel damp and keep out frost frequently results in too high a temperature being maintained. An ordinary greenhouse should be kept at 40° to 45° by day artificially in severe weather and 40° at night. The plants are quite safe provided the temperature does not fall below 35°. Ventilation should commence when the sun raises the temperature above 45°. Watering must be done in the morning, and though lessened supplies will be necessary the plants can be examined at least every other day.

Liliums.—These should be potted before they begin forming fresh roots—indeed, some are never entirely dormant. The earliest *L. auratum* and *L. longiflorum* will be fast pushing fibrous roots, and must not be disturbed; but if in pots already large enough merely remove the surface soil and dress with fresh, seeing that the drainage is in good order, but in case the pots are too small transfer to larger without disturbing the roots. Both these *Liliums* are impatient of drought at the roots, but it is essential that the soil be not made and kept very wet. *L. speciosum* (*lancifolium*) vars. should also be repotted, and have the soil moist, keeping them where they will be cool but safe from frost. Turfy loam chopped up moderately small, a sprinkling of sand, and enriched with a fourth of leaf soil or thoroughly decomposed manure, will suit them well, draining the pots and leaving space in the pots for top-dressing after the plants have formed fresh shoots.

TRADE CATALOGUES RECEIVED.

James Dickson & Sons, Newton Nurseries, Chester.—*Catalogue of Forest Trees and Shrubs.*

Kelway & Son, Langport, Somerset.—*Catalogue of Gladioli.*

Thomas S. Ware, Hale Farm Nurseries, Tottenham, London.—*Catalogue of Trees and Shrubs, and Choice Bulbs.*

Cranston's Nursery and Seed Company, Limited, King's Acre, Hereford.—*List of Trees and Shrubs.*

* * All correspondence should be directed either to "The Editors" or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Book (*A Young Gardener*).—Thompson's "Gardener's Assistant" is published by Messrs. Blackie & Son, Paternoster Buildings, London, and at Glasgow and Edinburgh. The last edition was edited by Mr. Thomas Moore.

Japanese Names (*A. P.*).—We know of none that approach to the English names of plants. *Ebui* is synonymous with our *Flower*; *kina* is grass; and *shinrichi* a root.

Cucumber (*Stephen Castle*).—The fruit you have sent is an excellent one for this season of the year, and is of superior quality. It testifies to the soundness of your culture, described on page 369.

"Herefordshire Pomona" (*A. F.*).—In our reply last week an error occurs relative to the price of this work. The first part only is 15s., the other two are 21s. each.

Stocks for Apples (*Holwell*).—The best stock for standards is the Crab, and for dwarfs the Paradise. There are several varieties of the Paradise stock, Rivers' Broad-leaved being a very good one, so is the Nonsuch. The French Paradise is a weak grower, and short-lived in many soils.

Stove Heating (*W. H. W.*).—We do not think that an ordinary-sized stove would heat the flue sufficiently for affording the requisite bottom heat for Cucumbers early in the season; but a large stove would doubtless afford heat that would be useful in the manner indicated, the flue being made with sanitary pipes.

Vine Roots Unhealthy (*W. M.*).—There are no traces of Phylloxera upon the roots you sent, and probably the chief cause of their unhealthy appearance is that the soil is too heavy, at least such seems to be the case with soil enclosed in the bottle. You give us no particulars as to the position of the house or the general condition of the Vines, and consequently we are unable to reply more explicitly. Renewing and well draining the border would no doubt improve the health of the Vines.

Preparing Ground for Roses (*Student*).—Trench the ground at once 2 feet deep, bringing some of the lighter soil to the top, and mix it with the surface soil, which you say is very stiff. Digging now cannot make it more adhesive, but exposure to frost will pulverise it, and you may make it more friable by adding sand. In trenching throw it into ridges, and as roughly as possible, so as to expose it to frost. If you cannot obtain sand, ashes will answer the purpose of making it more open.

Stopping Ficus elastica (*Clifton*).—You may take out the point of the shoot without injury to the plant, only you will spoil its appearance, as buds will start from the lower joints. Why not wait until spring? then take off the top with a couple of joints and the growing point, and if inserted in sandy soil it will strike freely in a hotbed. Cut the stem off two or three eyes from the soil, and the lower part will break freely and soon become furnished with fresh foliage. Every eye taken off with a portion of wood and its accompanying leaf will strike freely in bottom heat.

Moss on Gooseberry and Currant Bushes (*Oscar*).—It would be desirable to remove the moss, and you should do so at once, and, after scraping off all you can take off the soil round each bush as low as the roots, but without injuring them, replace it with about four good spadefuls of manure, and then cover the manure with the soil removed, or part of it, not burying the stem too deeply. You may then wait until the first rain, and whilst the bushes are wet dust them thoroughly in every part with fresh-slaked lime. It will destroy the moss, and be less tedious of application than washing them with lime and soot. The lime-dusting may be repeated early in spring before the buds open.

Zonal Pelargoniums for Winter (*E. B.*).—The plants require to be grown well through the summer in cold frames with the lights drawn off during all favourable weather, so that the growth is sturdy. The shoots may be topped till August, and after that time the flower buds should be removed as they appear until October. They must be grown generously and the roots be always active. As the autumn approaches they must be placed in a very light position in a house having a temperature of 45° to 50°, with as much air as the outside temperature permits. By giving them liquid manure occasionally they will flower all the winter in a suitable structure.

Potatoes and Popery (*Curio*).—Prejudices have usually accompanied new introductions, but we do not remember the singular connection of "Potatoes and Popery" being alluded to, except in the following manner in Roberts's "Social History of the People of the Southern Counties of England"—"Potatoes were a luxury until 1765, when Lord Sheffield bought some, and soon after farmers began to plant them in the fields. This novelty experienced the usual fate—viz., that of exciting prejudice against it. At an election at Lewes Potatoes shared with popery the indignation of the people, and "No Popery! No Potatoes!" was the popular cry. Potatoes excited so much prejudice in France, from a belief they would bring back leprosy once more, that the growing crop required to be watched for protection."

Euonymus europæus (*J. R. P.*).—The specimen sent is the fruit of the Common Spindle Tree (*Euonymus europæus*), so called from its wood being used long ago for making spindles. It is called Prickwood and Prick-timber, from being used for toothpicks and skewers. The wood is said to be used by musical instrument makers. For skewers and toothpicks the wood should be cut when the shrub is in bloom, for then it is tough and not easily broken; it is also used by watchmakers for cleaning watches. The berries act as an emetic and purgative, and are fatal to sheep; and when powdered and sprinkled on the hair destroy pediculi; sometimes it is made into an ointment for the same purpose. No animals except the goat will browse upon the plant. It is surprising how few persons know this plant, as we very frequently receive specimens to name.

Shading Conservatory (*W. C.*).—What you can need a permanent shading for is inexplicable, as except during the summer months when the sun is powerful shading is not only unnecessary, but from September to April absolutely injurious. Indeed the necessity of affording light during the autumn, winter, and spring months induces gardeners to cut away the strong-growing roof climbers considerably to admit as much light as possible to the plants beneath. Within the time indicated plants, flowering or otherwise, cannot have too much light, and instead of being shaded they should have the roof and side lights thoroughly cleaned to admit of every ray of light possible passing through the glass for the benefit of the plant. Perforated zinc is much too dense a shading at any time, even for shade-loving plants. Summer cloud answers very well, and so does whitewash, and if placed on the inside of the glass will last a season. It can easily be washed off; it costs little beyond the trouble, and is not objectionable in appearance.

Propagating Erica mediterranea (*J. Surrey*).—Take cuttings of the young shoots when their bases are rather firm, stripping off the leaves from half the length of the cutting, and paring its base smooth, insert them round the sides of a pot. The pot should be filled half its depth with drainage and a little rough peat, and then to within three-quarters of an inch of the rim with very fine sandy peat, the whole being covered up to the rim with silver sand; water gently and press firm. After standing a few hours insert the cuttings, and place them in a cold house or pit covered with a hand or bellglass. Keep them close and moist, shading so as to lessen the necessity for watering; and when the cuttings have struck, as you may know by their growing, admit air gradually. Pot them off when well hardened, and keep them in a cool house or pit over the winter, planting out in the spring. They may also be wintered in the cutting-pots, and planted out in spring after being well hardened.

Forming Pyramid Cherry Trees (*D. Wilson*).—Commencing with a maiden plant, the head should be taken off at 13 inches above the point of union of the graft and stock. This will cause the production of side shoots, the uppermost of which is to be trained as a leader, and all the others should have their points taken out as soon as they have made six leaves, commencing with the strongest and ending with the weakest; when the shoots push again take out their points at the third leaf. The leader may be stopped when it has grown 12 inches, and it will push one or more shoots. One is to be trained as a leader, and the others should have their points taken out at the third leaf. In winter the leader should be cut back to within about 15 inches of the last stopping, and any of the side shoots that are irregular may be shortened so as to have the tree widest at bottom and gradually tapering upwards. As respects the leader the treatment is the same in the following year, and afterwards, until the desired height of tree is attained, and the side shoots are allowed to make shoots with six leaves; then take out their points, keeping them closely pinched-in afterwards to one or two leaves. Care must be taken to stop so as to form a perfect cone or pyramid, encouraging the shoots in the hollow places, and not stopping them until they are of equal length with the others, and when they are too prominent pinch more closely.

Dendrobium formosum (*J. Mason*).—It succeeds admirably as a pot plant like most others of the same genus. The pots are filled to two-thirds of their depths with corks, over which should be placed a mixture of chopped sphagnum, fibrous peat, lumps of charcoal, and a little silver sand, with corks, the whole compressed firmly and rising well above the rim. Let the roots of the plant alone be covered with the compost, when it is as much at home as if it were growing on the trunk of a tree. Being a native of Nepal and Moulinet it does not require a very high temperature, and will, indeed, grow in a warm vinery—an admirable place for a great number of Orchids. If the plant is in good health and in good growth, place it in a house with a temperature of 45° to 50°, and from now until March give only a sprinkling of water betimes to keep the pseudo-bulb from shrivelling up. In March you may put it in a vinery with a temperature of from 50° to 55°, increasing in a few weeks to 60° at night, and also sprinkle it overhead every morning for the first fortnight, when it will start into flower and afterwards into new growth. It should now be encouraged with moisture to make a good growth, and on that being completed and the pseudo-bulbs being firm, keep it dry and moderately warm, but try to obtain a complete maturation by exposure to light and air.

Marechal Niel Rose Canker (*J. P.*).—We have seen it canker both on the Briar and Manetti stocks, and it does not always grow freely on its own roots. Relative to a stock for this Rose a correspondent communicated the following note last January:—"I have seen this beautiful Rose grown on many different stocks, such as the Félicité Perpetuelle, Margottin, seedling Briar, Gloire de Dijon, and several others, but the De la Grifferaie stands first in my estimation. I have seen the Marechal on this stock throw up shoots 8 to 10 feet long, and as for canker I have no reason to think it will do so. The buds are so firmly united to the stock that it is a difficult matter to pull them out. In looking over Messrs. Wm. Paul & Son's nurseries at Waltham Cross I observed hundreds of Marechals on the De la Grifferaie stock, and it was astonishing to see the growth they had made in one year—three or four shoots 6 to 8 feet long. I noticed also such varieties as Gloire de Dijon, Climbing Devonensis, Belle Lyonnaise, Madame Bernard, Mlle. Marie Berton, and Cloth of Gold growing on this stock with remarkable vigour. I strongly advise all who find it difficult to grow this king of Roses to give it a trial on the above-mentioned stock, and I am sure they will be well rewarded for their trouble." If the plants are budded on the Manetti the buds should be inserted close to the roots, and the plants will speedily be on their own roots. We have recently seen some Marechal Niel Roses raised from cuttings that have produced growths 20 feet long this year.

Names of Fruit (*E. K.*).—1, Uredale's St. Germain; 2, Chaumontel; 3, Beurré Diel; 4, Thompson's; 5, Comte de Lamy; 6, Duck's Bill Apple. (*J. B. D.*).—1, Winter Greening; 2, not known; 3, Northern Greening; 4, Tom Putt. (*John Laing & Co.*).—1, Herefordshire Beefing; 4, Leathercoat; 7, Bleuheim Pippin; 8, Royal Russet; 11, Surrey Flat Cap; 15, Beauty of Kent. (*Connyngham*).—1, Marechal de Cour; 2, Millot de Nancy; 3, not known. (*H. P. C.*).—Triomphe de Jodoigne. (*G. B. C. W.*).—Alfriston is a large green Apple traced all over with lines of russet. The specimens you sent are Beauty of Kent. (*Henry Smale*).—Apples.—2, Calville Blanche; 3, Pearson's Plate. Pears.—4, Beurré de Jonghe; 6, Beurré d'Arenberg. A large decayed Pear, delivered by the Great Western Railway, is King Edward's Pear. We have no name of the sender. (*R. H.*).—Nouveau Poiteau. (*H. W.*).—The Grapes were so shaken in transit and crushed as to be quite beyond identification. Grapes cannot be named unless fair representative bunches are sent and arrive in good condition.

Names of Plants (*S. T.*).—Adiantum macrophyllum. (*E. D. S.*).—We fail to recognise the plant sent, as the flowers were completely withered; it appears to be a Liliaceous plant. (*R. T.*).—Meyenia erecta. (*J. R. Pearson*).—Euonymus europæus.

POULTRY, PIGEON, AND BEE CHRONICLE.

BREEDS OF CATTLE ADAPTED FOR DAIRY FARMING.

(Continued from page 470.)

HAVING previously noticed the different breeds of cattle as pure-bred stock, we must now allude to the cross-bred cows exhibited at the late Dairy Show. It is very useful and important to notice the effect of crossing or mixing the different breeds of cows intended for dairy purposes and their progeny, and we think that in

such a class the breed of animals upon which the cross is based ought not only to be stated but certified, in order that the home farmer and others may be taught thereby in their breeding of dairy cattle. Unless this is done there is frequently such an affinity to one breed or the other that the animals appear to a superficial observer to be pure-bred instead of cross-bred, as was the case this year with a fine roan cow exhibited as cross-bred, which would really have passed muster as a Shorthorn, not eligible as pedigree stock. It will therefore be readily understood that the animals should be specifically named as a cross between such and such pure breeds. It is further a well-known fact to experienced men that it is not necessary to have a pure-bred animal of any breed to insure a first-class milker, because excellent milking stock is to be obtained under numerous strains. The chief variation appertaining to particular breeds is to obtain quality of the milk, and when this and quantity can be combined in one animal we have an example worth imitation, no matter what the origin may be, but it is this fact which renders it desirable that the origin both of sire and dam should be certified.

We must fall back upon our own experience and that of some of the most intelligent of cattle breeders to explain fairly the difficult task of combining quality and quantity of milk with correctness of form of the animals. In our case we have never been enabled to obtain such a combination as we have named in a cross between the Shorthorn and Jersey, especially if the sire was of the former breed. If, however, the Jersey bull is used for the Shorthorned cow the result will be better; but even in such case we have never succeeded to our satisfaction, in consequence of the stock being so small, light, and various. On the other hand, when we have used the Guernsey bull for the Shorthorned cow, and both coming of good milking strains, we have been well satisfied, and have certainly possessed some of the finest milking dairy cows we have ever seen, both as great milkers and yielding rich cream adapted for making butter of the finest quality, and at the same time milk for making superior cheese, without the necessity of using "annatto" for the purpose of colouring the goods. This colouring used to be considered of much more consequence by the London cheesefactors twenty or thirty years ago than at present, hence the necessity of using "annatto" for the purpose, as shown by the fact that in 1858 £2000 per year was paid for this article in the county of Cheshire alone. There is no danger in using this deleterious substance so long as it is properly mixed in moderate quantities in the cheese, but when used by the ignorant it has often proved damaging to the quality of cheese, if not injurious to the health of the consumer. It will therefore be readily admitted how very desirable it is to have the cheese coloured by the supply of milk of high colour and rich quality, so that the fashion of the London cheesefactor may be met, and at the same time an article of the richest possible quality may be available for the consumer, who is always willing to pay a good price for a superior cheese.

It is notorious that to the dairymen of Bucks, Derbyshire, Salop, and the west of England the graziers of the eastern counties are indebted for many of the cross-bred animals met with, for they look out for the cow that gives the most milk or butter, or promises to make the greatest quantity of cheese, quite regardless of her origin; nor in many cases are they much more careful as to the pedigree of the bulls, in consequence of their selling the calf at a few days old. There is, however, now a growing desire among them to use a well-bred bull, whereby they will much improve the produce, especially where they intend to rear heifer calves to keep up the stock, because a well-bred bull from a good milking family will soon alter the appearance of the herd. We find an instance worth recording in a statement made by Mr. J. Coleman, farm steward to the Duke of Bedford at Woburn Abbey,

in 1862, where a herd of from thirty to forty pure Hereford cows were kept, and still a large quantity of milk and butter required. He says, "I have found it quite impossible to improve the herd in milking and fattening or flesh-producing qualities at the same time, and had often to sacrifice a very fine cow because she gave no milk, or others that were good milkers but unfit to breed a show ox. Finding out, then, that it was almost impossible to unite the truth of form and aptitude to fatten, according to our present standard with a profitable dairy, I thought it desirable to keep two herds—one for breeding purposes (the dams only rearing their own calves), and the other for dairy purposes. I have been often asked if I would go in any farther than the first cross between two distinct breeds. I think it best not to do so, as I have always found the produce of the cross-bred cow to be very inferior to herself." As we have distinctly advocated a cross-bred animal between the Shorthorn and Guernsey, we desire to say that it is chiefly for butter-making and milking, but not always for cheese-making, as on some soils the produce may be too rich in cream, and if it is found to be so the course is then open to use a proportion of Guernsey cows, say 20 to 25 per cent., for the purpose only of colouring the cheese. We have not yet obtained Dr. Voelcker's analysis of the milk yielded by cows at the late Dairy Show, and cannot give it this week, as we intended.

GOATS.—We must now refer to another phase of the late Dairy Show—viz., the exhibition of goats, as stock calculated for the production of milk. Until recently goat-keeping in this country has been a very small and insignificant affair. It has now, however, assumed large proportions through the formation of a Goat Society and so many shows having been held during the past six or seven years, with prizes awarded for the animals best adapted for milking purposes, fancy animals only having previously attracted notice. The propagation of goats will now no doubt settle down into the breeding of those best adapted for yielding the most and the best quality of milk ; and as the animals become more generally kept, especially by persons residing in the suburban districts of the metropolis and other large towns, the selection and crossing of the various breeds will no doubt rapidly advance in the direction we have indicated. In those cases where a small quantity of pasture or even ornamental land is held no doubt the goat will gain a footing where the desire to keep a cow has been out of the question, and it must be remembered these animals will live partly upon the trimmings of vegetables of almost any kind, and by judicious feeding with bran and other substances added to refuse vegetables of the garden the latter will be turned to better account than by keeping swine only for that purpose. There has been, however, one matter operating against goat-keeping—the unpleasant odour which attaches to the male animal. This objection, however, will be met by the crossing or using male animals which are entirely devoid of the drawback, which is the case with the Angora male, a variety imported from the Cape for the purpose of crossing with our present stocks, which will in all probability result in the diminution of the existing objection, and by special methods of selecting the animals for crossing may ultimately be removed entirely. It appears to us that it would be best to select animals without horns if they can be found to possess equal advantages of milking, &c., with the horned varieties. At the late Dairy Show, for instance, in the Polled class there were eleven entries, and the competition very keen. The first prize was awarded to Mr. J. Arnold's Brown Kate, carrying a splendid udder with long teats, capable of being easily handled. This we deem a very important point in the future breeding of animals for dairy purposes, and will no doubt lead to crossing between such varieties as will eventually furnish us with animals which now only exist in our imaginations and aspirations. The varieties of goats are more numerous than may be supposed, and as the interest in keeping them increases it will become more instructive to inquire into the capacity of each breed to answer our purposes for milking as well as the flesh for consumption, for certain breeds are certainly under proper feeding, &c., capable of yielding meat equal if not superior to much of the mutton consumed in this country. Now, as we shall not have sufficient space in this article to elucidate all matters relating to the goat tribe we hope on a future occasion to make it a special subject, but now only to name some of the best varieties. These consist of the Angora, Cashmere, Nubian or Egyptian, the Maltese, and others. The largest Angora males will sometimes yield a fleece of mohair, weighing as much as 12 or 15 lbs., of considerable value. The flesh, too, closely resembles mutton, whilst its milk, though less in quantity than some other varieties, is much richer. The Nubian is a breed much esteemed in France, and is an extraordinary milker, the cross-bred stock yielding on the average six and a quarter pints per day, whilst the pure breed yield eight pints per day. The Maltese are good milkers and

extremely docile, it being the custom in Malta for the animals to be driven in small herds through the streets and milked at the doors of the houses, before which they stop as regularly of their own accord as the butcher-boy's horse does here when calling for orders. Milking these animals is always performed from the rear, which with their long narrow udders is much more convenient, and it is imagined by some fanciers that a cross would be desirable between the Nubian and Maltese varieties. In conclusion we will give the comparative analysis between cows' and goats' milk, by Dr. Vocleker, in 1879.

In the month of July, from a Cow of Sir H. Dashwood's, Kirtlington Park, Oxon.
 " " from a Goat without horns, five years old, of Mr. Stephen
 Dickens', Holloway Road, N.

	100.00	100.00

WORK ON THE HOME FARM.

Horse Labour.—On those farms where the Wheat has been all sown the winter fallowing for Barley or roots next spring will be necessary—that is to say, the deep ploughing for the land to lie high and dry during the winter months. Before this deep ploughing is done it is necessary that the lumps of couch upon the autumn-fallowed land should be lifted off the surface by the use of Howard's patent self-lifting drag, in order that it may be forked or raked together and carted away, for burning in the field is seldom practicable in the month of November. This is best done before the deep fallow-ploughing takes place. On the stubbles which come in course for Barley or roots there is often only a few bunches of couch to be seen, but these should be forked out before ploughing the land for a winter fallow, as the farmer must remember the first cost in removal of couch is always the least. Some farmers say such a small quantity of couch will work out during the spring ploughings, &c., but this is just the point to which we wish to call attention by asking, Are these spring ploughings required if the land is clean? We say No, and that as a preparation for either Barley or roots the less the land is ploughed in the spring the better. The past seedtime for Mangolds illustrates this in a remarkable manner, for where the land was ploughed at the seedtime, the weather being so dry afterwards, the seed did not vegetate well; whereas the land which was spring-tilled with the scarifier only lost no moisture and the plants came well together, resulting in a splendid crop of roots. This is the time of year when earth from the farm roadsides should be carted to heap, and from the highways and parish roads much valuable earth may be stored away for future use in cattle boxes, horse boxes, pig pens, &c.; in fact, wherever animals are accommodated under cover earth should always be placed under them, for the double purpose of ensuring their health and the production of manure.

Hand Labour.—Some men and women will be engaged in forking out couch and collecting it on the fallows after they have finished the work of taking up and storing the root crops, or by pitting them in small heaps in the field for use in the spring. This latter plan answers admirably, as a crop of roots cannot be allowed to remain in the land during the winter months owing to the attacks of game or wood Pigeons; besides, the roots are sure to lose quality by remaining in the land until the spring.

At this time of year all the breeding flocks of ewes will be in a more or less advanced state of pregnancy, and it is only right they should receive moderate and regular feeding, especially of roots, but of good old lea grass if possible, with a constant change of pasture which is necessary, not only as a food question, but likewise on account of the health of the animals, moderate exercise being essential for all breeding stock. Swine of all ages will require special attention now, not only in feeding but in the littering of well-arranged pens. This, however, applies more particularly to farrows of little pigs and to fattening pigs. The breeding sows we find are best cared for when they have a sheltered hovel to lie in, with a run at daytime in a well-arranged farmyard or a paddock, where they may receive the usual trough food and roots *ad libitum* strewed over the yards. Fattening pigs we have always found will yield most profit when they are fed with pulped roots and meal. The meal should be mixed with a large portion of roots at first and gradually diminishing the quantity, giving meal only at the completion of the period of fattening. The meal used may be either of Maize or Barley, with a portion of bean or pea meal. This latter addition will yield more flesh in proportion to the fat, making the meat more valuable to the butcher and consumer. It must not, however, be forgotten that the price of the meal should regulate the proportion in which it is used.

In noticing the pastures in general, we see many bunches and patches of grass which have been refused by the cattle up to this time, but in order to induce them to eat it during the winter months the best plan is to give a liberal dressing of salt strewed on the

bunches and patches of the sourest grass. The cattle will not only eat it with relish but it will be far more nutritious for them, either young stock or dairy cows, but especially the latter.

In many districts the dairy cows will be maintained almost entirely in their stalls and pens, and will be dependent chiefly upon roots, hay, and cake. We think that the time and manner of feeding is of great consequence, and that roots and cake meal should be given immediately after milking, and a full allowance of water just before milking. Roots such as Swedes will sometimes impart a flavour to the milk and butter; the feeding just after milking avoids this to a great extent. The cattle of different ages now feeding under cover should receive common Turnips, then hybrid yellow Turnips, and Swedes in succession. At any change of food, however, it is a good plan to mix the roots before any decided change is made, as the cattle will not only eat them better but are not so likely to scour them, as any sudden change frequently does. Carrots and Carrot greens are both valuable; the latter should never be wasted, but given to young cattle. Calves and yearlings will do better with these than when eating Turnips, &c. Cabbage is, however, best for them, but whilst the digging and lifting of Carrots is going on the greens should be used daily as fast as they are available. Farm horses should have a good allowance of Carrots, for much hard work is yet to be accomplished before the dead portion of winter work arrives. About 12 or 15 lbs. of roots given twice daily will be sufficient, with Oats or drege and hay, for horses will always prove more healthy if fed on a moderate allowance of roots throughout the winter.

CRYSTAL PALACE POULTRY SHOW.

(Continued from page 472.)

Spanish curiously enough numbered the same as last year—forty-two pens in all. They were good even classes, but the old birds, especially the hens, were hardly through their moult. Old cocks were only five. First was a little rough in quality of face and had a slightly drooping comb. Second was better in both these points, but a trifle close in eye; we preferred him to the first. Third had the largest face and lobe of any, but rough. In hens (six) all three winning birds were throughout of good quality, somewhat shrunken in face and comb through moult. 779 (Le Sueur) although small should, we thought, have won on account of her splendid condition and flat rounded lobe. In cockerels (seventeen) the winner also took the cup for male birds. He is grand in size and shape, a nice face and long earlobe, both of good quality; comb not quite straight—an easy win. Second large, but with a fold in earlobe and rather rough in face. Third, nice smooth face and lobe, and very perfect comb, 786 (Dixon), highly commended, very long but not broad enough in lobe. The class contained several other good birds. Pullets (twelve), the winner here took the cup for hens or pullets; we did not fancy her so much as second. Her face was uneven over the eyes, and there was a fold in each earlobe. Second had a nice smooth face and large rounded earlobes. Third had a face small but good; she failed in body. 805 (Mills), very highly commended, we much liked; her face was one of the largest and best laid on in the class.

Leghorns were shown in four classes, old and young competing together. They numbered forty-six as against sixty last year. The greater part of the falling-off was in the Whites. Brown cocks (fourteen) were a nice class. The winner splendid in shape and very rich in colour, but with an enormous comb and not quite clear in lobe. Second very smart in carriage and well striped in hackle; comb smaller than first, but still coarse. Third was in magnificent bloom, his colour rather dark but brilliant, best in comb and clear in lobe. All three winners were birds of the year. Brown hens (fifteen).—The prizes here also went to chickens. First was good in lobe, shape, and colour; second not so good in lobe and too dark in colour, but larger; third in the best condition of the three, but too brown. Rest of class moderate. White cocks (ten).—First and Leghorn cup a neat shaped bird, good in comb, moderate in lobe, but seemed to us, in the failing light in which we saw him, to be rather yellow. Second was a good one but for an imperfectly closed beak. Third long and rather slim in body, but very even in comb; this, however, was set on too low at back. White hens (eight) were not remarkable as a class. First and second nice pullets, the former winning by condition; third a good hen.

Andalusians were by themselves this year, the Minorcas being relegated back to the variety class (why, we don't know). They numbered thirty-seven as against forty-two of both breeds last time. The cocks (seventeen) were a very fair lot, nearly all being of this year. The winner, who also took the cup, was good in size and pencillings but rather rough in comb and stained on lobe. His hackle feathers were of the medium colour. Second darker in colour, pale in face, and rather loose in comb, but in prime condition. Third medium colour again, face pale and comb folded in front, otherwise of the right sort. The hens were a strong class of twenty. First an old bird of the light shade nicely pencilled. Second another good one of similar type. Third smaller and rather cloudy in colour. 1448 (Wilson), very highly commended, a good one out of show form.

We append the complete prize list; we regret that our reporter's notes on the Pigeons arrived too late for insertion.

POULTRY.

DORKINGS.—*Coloured.*—Cock.—1, L. Pilkington. 2, J. Collins. 3, R. W. Beachey. Hen.—1 and Cup, J. Taylor. 2, P. Ogilvie. 3, B. Smith. 4, Mrs. Gunn. *vhc*, F.

Parlett. *Cockerel.*—1 and Cup, A. E. W. Darby. 2 and 3, J. A. & M. F. Smyth. 4, E. Barker. 5, W. H. King. *vhc*, B. Smith. R. W. Beachey. L. Pilkington. W. H. King. *Pullet.*—1 and Cup, O. E. Cresswell. 2, B. Smith. 3, W. H. King. 4, Earl of Winterton. 5 and *vhc*, J. A. & M. F. Smyth. *Silver-Grey.*—Cock.—1 and Cup, B. Smith. 2, P. Ogilvie. 3, Miss Pasley. *vhc*, Miss A. Peel. Hen.—1, Mrs. Radclyffe. 2, P. Ogilvie. 3, B. Smith. *Cockerel.*—1 and Cup, O. E. Cresswell. 2, J. Cranston. 3, F. Cheesman. *Pullet.*—1, J. Cranston. 2, O. E. Cresswell. 3, P. Ogilvie. *vhc*, Mrs. Wachter. G. Haddock. *Blue or Cuckoo.*—1, P. Roffey. 2, Countess of Dartmouth. 3, W. Virgo. *White.*—Cock.—1 and Cup, Mrs. M. A. Hayne. 2, J. E. Pilgrim. 3 and *vhc*, Rev. R. S. S. Woodgate. Hen.—1, W. Badger. 2, A. H. Longman. 3, Rev. F. Tearle. *vhc*, Rev. R. S. S. Woodgate. *Any variety.*—1, C. Cork. 2, W. Virgo. 3, Earl of Winterton. 4, H. Stephens.

COCHINS.—*Cinnamon or Buff.*—Cock.—1, H. Lingwood. 2, G. H. Proctor. 3, C. Brown. *vhc*, C. Brown. W. Wright. Hen.—1 and Cup, H. Tomlinson. 2, C. Brown. 3, Mrs. T. Pyc. *vhc*, C. Bloodworth (2). *Cockerel.*—1 and Cup, A. E. M. Darby. 2, H. Tomlinson. 3, D. Bragg. 4, Mrs. Davidson. *vhc*, C. Brown. J. Hine. H. Tomlinson. G. H. Proctor. *Pullet.*—1, H. Lingwood. 2, C. Brown. 3, C. Bloodworth. 4, Mrs. Davidson. *vhc*, Mrs. Davidson. A. J. E. Svyndell. Mrs. W. Paxon. G. H. Proctor. C. Bloodworth. Mrs. Lang. *Partridge.*—Cock.—1 and Cup, R. P. Percival. 2 and 3, R. J. Wood. *vhc*, J. Turner. Hen.—1, E. Tudman. 2, R. Southern. 3, R. P. Percival. *vhc*, R. J. Wood. *Cockerel.*—1, Rev. E. H. Morgan. 2, F. Nettlefold. 3, C. Sidgwick. *vhc*, T. C. Morris. J. Turner. *Pullet.*—1 and 3, R. J. Wood. 2, F. Nettlefold. *vhc*, T. Sharpe. J. Collins. R. Southern. W. Rutledge. R. J. Wood. *White.*—Cock.—1, R. P. Percival. 2, H. Tomlinson. 3, C. Thompson. Hen.—1 and Cup, R. P. Percival. 2, G. H. Wood. 3, J. Turner. *vhc*, C. Thompson. *Cockerel.*—1 and 2, A. E. W. Darby. 3, J. Turner. *Pullet.*—1 and 2, A. E. W. Darby. 3, G. H. Wood. *Black or Langshan.*—Cock.—1, G. H. Proctor. 2, A. E. W. Darby. 3, Mrs. J. T. Holmes. Hen.—1, J. Turner. 2, A. E. W. Darby. 3, T. Aspden. *Cockerel.*—1, Cup, and 2, W. Badger. 3, A. E. W. Darby. *Pullet.*—1 and 2, A. E. W. Darby. 3, H. J. Storer. *Any variety.*—1, C. Brown. 2, C. Sidgwick. 3, R. P. Percival. 4, R. R. Fowler & Co. *vhc*, A. E. W. Darby, Cockroft & Ashby, Lady Gwydyr.

BRAHMAS.—*Dark.*—Cock.—1 and Cup, Rev. G. W. Joyce. 2, L. C. C. R. Norris. 3, C. Tindall. 4, T. Aspden. *vhc*, A. Comyns, jun.; E. Kendrick, jun.; L. C. C. R. Norris. Hen.—1, Miss E. Cotes. 2 and 3, R. P. Percival. 4, T. Sharpe. *vhc*, Rev. T. C. Peake. E. Kendrick, jun. *Cockerel.*—1, Cup, 2, 3, and 4, H. Lingwood. 5, R. P. Percival. 6, A. Comyns, jun. 7, Miss E. Russell. *Pullet.*—1 and Cup, L. C. C. R. Norris. 2, W. Wright. 3, Lady Gwydyr. 4 and 6, R. P. Percival. 5, H. Lingwood. *vhc*, E. Pritchard. F. Bennett. H. Lingwood. *Selling class.*—1 and *vhc*, E. Kendrick, jun. 2, Lady Gwydyr. 3, R. P. Percival. 4, Miss E. Shuter. *Light.*—Cock.—1, Cup, and 2, R. P. Percival. 3, A. J. Thurlow. 4, G. H. Wood. Hen.—1, H. Lingwood. 2, Lady Gwydyr. 3, J. Bloodworth. 4, Rev. G. F. Davies. *Cockerel.*—1 and Cup, P. Haines. 2, W. F. Potter. 3, G. B. C. Beeze. 4, S. Lucas. 5, J. F. Hall. 6, H. C. White. *Pullet.*—1 and Cup, F. Nettlefold. 2, J. T. Holmes. 3 and 6, L. C. C. R. Norris. 4, H. C. White. *Selling class.*—1, J. & W. Birch. 2, G. B. C. Beeze. 3, Lady Gwydyr. 4, J. W. Windred. 5, F. Nettlefold. *Dark or Light.*—Hens or Pullets.—1, G. B. C. Beeze. 3, W. F. Potter. 3, E. Kendrick, jun. 4, Miss E. Shuter.

SPANISH.—Cock.—1, W. R. Bull. 2, J. Boulton. 3, Lady Allsopp. *vhc*, P. F. Le Sueur. Hen.—1, 2, and 3, F. M. Chatterton. *vhc*, Lady Allsopp. *Cockerel.*—1 and Cup, H. Brown. 2, J. Woods. 3, J. Boulton. *vhc*, W. R. Bull. J. Francis. S. T. Nash. *Pullet.*—1 and Cup, J. Woods. 2, W. R. Bull. 3, S. T. Nash. *vhc*, J. F. Dixon. D. M. Mills. P. F. Le Sueur.

HOUDANS.—Cock.—1, Mrs. Irving. 2, C. Howard. 3, E. Wingfield-Stratford. Hen.—1 and Cup, E. Wingfield-Stratford. 2, H. Howard. 3, W. Nickolls. *vhc*, E. Wingfield-Stratford. T. Fullarton. *Cockerel.*—1, W. H. Copplestone. 2, E. Wingfield-Stratford. 3, M. W. L. Brooke. 4, Rev. H. B. Beedham. *Pullet.*—1, S. W. Thomas. 2, W. Nickolls. 3, E. Wingfield-Stratford. 4, Mrs. D. Lane. *vhc*, E. Wingfield-Stratford (2). Mrs. D. Lane. Mrs. S. W. Thomas. Rev. W. Pearce.

CREVE-CŒURS.—Cock.—1 and Cup, Dr. N. Jackson. 2, W. R. Park. 3, R. Pound. Hen.—1, Dr. N. Jackson. 2, A. E. Ward. 3, W. R. Park. *vhc*, J. J. Malden. *Cockerel.*—1, Dr. N. Jackson. 2, T. Fullarton. 3, M. Hall. *Pullet.*—1, A. E. Ward. 2, M. Hall. 3, T. Fullarton.

LA FLECHE.—1, T. B. Lowe. 2, —Bagg. 3, T. Swinburne.

HAMBURGHES.—*Golden-spangled.*—Cock.—1, S. Fielding. 2, R. W. Braeewell. 3, C. May. Hen.—1 and Cup, J. Rawnsley. 2, H. Beldon. 3, G. Randall. *vhc*, J. Jackson. *Silver-spangled.*—Cock.—1 and Cup, H. Beldon. 2, J. Rawnsley. 3, Rev. S. Ashwell. *vhc*, J. Preston. Hen.—1, H. Beldon. 2, W. R. Park. *vhc*, Ashton and Booth. *Golden-pencilled.*—Cock.—1, H. Beldon. 2, J. W. Kelleway. 3, O. E. Cresswell. Hen.—1, W. Driver. 2, H. Beldon. 3, W. L. Bell. *Silver-pencilled.*—Cock.—1, Mrs. E. G. W. Lenchford. 2, J. Rawnsley. 3, H. Beldon. Hen.—1, H. Beldon. 2, W. L. Bell. 3, J. Rawnsley. *Black.*—Cock.—1, C. Hobson. 2, T. Mallinson. 3, W. L. Bell. *vhc*, C. Pemberton. J. Rawnsley. Hen.—1 and 3, W. L. Bell. 2, C. F. Copeman. *vhc*, J. W. Kelleway. H. Beldon.

GAME.—*Black-Red.*—Cock.—1 and Cup, S. Matthew. 2, T. P. Lyon. 3, G. Carrington. Hen.—1, S. Matthew. 2, J. H. Caton. 3, T. P. Lyon. *Cockerel.*—1 Cup, and 2, S. Matthew. 3, J. Colgrove. 4, H. E. Martin. *Pullet.*—1 and Cup, D. Harley. 2, T. P. Lyon. 3, H. M. Maynard. 4, J. Goodwin. *Brown-Red.*—Cock.—1, J. Mercer. 2, C. A. Bothway. 3, J. Robinson. Hen.—1, J. Mercer. 2, Capt. H. Heaton. 3, G. F. Ward. *vhc*, H. E. Rawson. *Cockerel.*—1 and Cup, J. Mercer. 2, J. A. Mather. 3, G. M. Bond. 4, C. Rowley. *Pullet.*—1, S. Matthew. 2, J. A. Mather. 3, J. Mercer. 4, H. E. Martin. *Duckwing.*—Cock.—1, T. P. Lyon. 2, S. Matthew. 3, D. Harley. Hen.—1, S. Matthew. 2, D. Harley. 3, T. P. Lyon. *Cockerel.*—1, D. Harley. 2, J. Goodwin. 3, T. P. Lyon. *Pullet.*—1, W. Kitson. 2, T. P. Lyon. 3, D. Harley. *Any other variety.*—Cock.—1, J. Wright & Pearce. 2, J. Colgrove. 3, J. T. Theobald. Hen.—1, J. A. Mather. 2, E. Walton. 3, R. Walker. *Cockerel.*—1 and Cup, Capt. H. Heaton. 2 and 3, J. Colgrove. *Pullet.*—1 and 3, J. Knowles. 2, J. A. Mather. *Any variety.*—1, J. Knowles. 2, J. Colgrove. 3, W. Sowerbutts.

MALAYS.—Cock.—1, E. M. Le Huray. 2, J. Coop. 3, C. E. Waring. Hen.—1 and Cup, G. Burnell. 2, Rev. N. J. Ridley. 3, J. Downing.

POLISH.—*Golden-spangled.*—Cock.—Cup, C. H. Huish. 2, W. Bearnley. 3, H. E. Broad. *vhc*, J. Partington. Hen.—1, J. Partington. 2, S. W. Thomas. 3, J. Dawson. *Cockerel.*—1 and 3, H. Jarvis. 2, J. G. Lenny. *Pullet.*—1, W. D. Osofo. 2, J. Dawson. 3, C. H. Huish. *Silver-spangled.*—Cock.—1, C. H. Huish. 2, A. Smith. 3, G. C. Adkins. Hen.—1, A. Smith. 2 and 3, G. C. Adkins. *Cockerel.*—1, J. Rawnsley. 2 and 3, A. Smith. *Pullet.*—1 and 3, G. C. Adkins. 2, A. Smith. *Black, or any other colour.*—Cock.—1, A. Perry. 2, H. Beldon. 3, J. Rawnsley. Hen.—1 and 3, H. E. Broad.

LEGHORNS.—*Brown.*—Cock.—1, W. Phileox. 2, H. Brown. 3, J. Hurst. Hen.—1, W. Phileox. 2, W. Kirk. 3, J. Hurst. *vhc*, J. Terry. *White.*—Cock.—1 and Cup, Mrs. Troughton. 2, Bradbury Bros. 3, R. R. Fowler & Co. Hen.—1, Bradbury Bros. 2, Mrs. Troughton. 3, R. R. Fowler & Co.

PLYMOUTH ROCKS.—Cock.—1, W. Adams. 2, R. B. Wood. 3, J. C. Fraser. Hen.—1 and Cup, J. C. Langton. 2, W. S. Evans. 3, A. Stevens.

ANDALUSIANS.—Cock.—1 and Cup, P. Bacon. 2, T. Lambert. 3, F. Winsor. Hen.—1, A. Stevens. 2 and 3, F. Winsor. *vhc*, Mrs. M. A. Wilson. 3, F. Winsor. *vhc*, Mrs. M. A. Wilson.

SULTANS.—1, Cup, and 3, C. Atkinson. 2, J. Rawnsley. 4, Mrs. C. M. Damant. *Chickens.*—1 and Cup, E. Nickolson. 2 and 3, C. Eyles. 4, Rev. J. P. Wright.

ANY OTHER DISTINCT VARIETY.—1, T. Ekins. 2, Mrs. M. A. Wilson. 3, Miss C. E. Palmer. *vhc*, J. Rix.

SELLING CLASSES.—*Dorkings, Brahmas, Cochins.*—Price not to exceed £2.—Cock or cockerel.—1, Rev. H. R. Peel. 2, S. Tuke. 3, Rev. T. C. Peake. 4, G. H. Wood. 5, W. Nickolls. *vhc*, C. Sidgwick, Miss Smithers. T. J. Saitmarsh. C. Bloodworth. Cockroft & Ashby. *Hens or Pullets.*—1, S. Lucas. 2, C. Brown. 3, H. Wilkinson. 4, W. J. Nichols. 5, H. Brown. *vhc*, J. Metcalfe. H. J. Storer. S. Lucas. *Cock and hen or cockerel and pullet.*—1 and 2, A. Atlee. 3, C. Sidgwick. 4, R. Cheesman. 5, G. C. Livett. *vhc*, E. Pritchard. S. Tuke. C. Brown. R. H. Langton. *Houdans, Creve, or La Fleche.*—Price not to exceed £2.—Cock or cockerel.—1, Mrs. A. Pigot. 2, P. Hanson. 3, Bentley & Clarke. 4, R. R. Fowler & Co. *Hens or Pullets.*—1, C. Howard. 2, W. Nickolls. 3, Mrs. A. Pigot. 4, J. E. Pilgrim. *Any other variety except Bantams.*—Price not to exceed £2.—Cock or cockerel.—1, P. F. Le Sueur. 2, C.

Bloodworth. 3, J. Richards. 4, H. E. Broad. 5, W. Bentley. *chc*, H. P. Jackson. *Hens or Pullets*.—1, J. Rawnsley. 2, J. Woods. 3, C. Bloodworth. 4, H. M. Maynard. 5, C. Green. *chc*, F. M. Ward. *Pile*.—*Cock*.—1, E. Walton. 2, F. W. R. Hore. 3, G. Vigers. *Any other variety*.—*Hen*.—1, E. Walton. 2, G. Vigers. 3, T. W. Anns. *BANTAMS*.—*Black*.—1 and Cup, S. Clapham. 2, J. W. & F. J. Crowther. 3, H. Stephens. *Japanese, any colour*.—1 and Cup, O. E. Cresswell. 2, F. B. Heald. 3, Hon. Mrs. A. Baillie Hamilton. *Schright*.—1, J. Bunelo. 2, M. Leno, jun. 3, Miss E. Browne. *Any other distinct variety*.—1, J. Rawnsley. 2, T. F. Phelps. 3, E. Walton.

DUCKS.—*Aylesbury*.—1 and 3, R. R. Fowler & Co. 2, Mrs. Gunn. *Pekin*.—*Drake*.—1 and Cup, J. W. Kelleway. 2, Mrs. H. M. Pease. 3 and 4, C. Howard. *chc*, W. Nickolls, Miss M. Jones, Capt. D. Bayley, F. Howard, R. R. Fowler & Co. *Duck*.—1, J. W. Kelleway. 2, W. Nickolls. 3, W. Bygott, jun. 4, R. R. Fowler & Co. *chc*, A. Perry. *Rouen*.—*Drake*.—1, D. Bragg. 2, T. Wakefield. 3, S. Burn. 4, R. Gladstone. *Duck*.—1 and Cup, F. G. S. Rawson. 2, W. Hulme. 3, J. Partington. 4, T. Tweedy. *chc*, W. Hulme, H. E. Rawson. *Black East Indian*.—1, Cup, and 3, Mrs. M. A. Hayne. 2, F. W. Earle. *chc*, Miss E. Browne. *Any other variety or Ornamental Waterfowl*.—*Pair*.—1, Mrs. A. Dresing. 2, A. Perry. 3, G. E. Smart. *Any variety*.—*Young Drake*.—1, A. E. W. Darby. 2, R. R. Fowler & Co. 3, W. Bygott, jun. *Young Duck*.—1 and 3, R. R. Fowler & Co. 2, T. Wakefield.

GESE.—1 and Cup, Smith & Sutcliffe. 2 and 3, Dr. E. Snell. *chc*, J. M. Spinks. *TURKEYS*.—1 and Cup, R. Gladstone. 2, Mrs. A. Mayhew. 3, J. & W. Birch. *SPECIAL CLASSES*.—*Cross-Bred*, suitable for the Table.—*Heaviest cockerel*.—1 and Cup, W. E. Warren. 2, E. Barker. 3, W. Leno, jun. *Heaviest pullet*.—1 and Cup, W. Nickolls. 2, M. Leno, jun. 3, Mrs. Walcher.

TABLEFOWL (CROSSBRED).—*Finesness of quality, smallness of bone, absence of offal, and closeness of plumage to be considered in preference to mere weight*.—*Couple of cockerels or couple of pullets (not Capons)*.—1, Cup and 2, W. B. Tegetmeier. 3, W. Bearpark. *chc*, M. Leno, jun.

PIGEONS.

POUTERS.—*Blue-Pied*.—*Cock*.—1, Cup and 3, Hon. W. Sugden. 2, E. Beckwith. *chc*, J. Baker. *Hen*.—1, J. T. Holmes. 2, E. Beckwith. 3, R. Fulton. *Black-Pied*.—*Cock*.—1, J. Baker. 2, J. T. Holmes. 3, F. W. Hodson. *Hen*.—1 and Cup, R. Fulton. 2, J. Dye. 3, F. W. Hodson. *Red or Yellow-Pied*.—*Cock*.—1, M. H. Gill. 2, Hon. W. Sugden. 3, E. Beckwith. *Hen*.—1, M. H. Gill. 2, E. Beckwith. 3, J. Baker. *White*.—*Cock*.—1, J. H. Smith. 2, W. P. Keall. 3, Hon. W. Sugden. *Hen*.—1 and 3, E. Beckwith. 2, W. P. Keall. *Any colour*.—*Young cock*.—1 and Cup, T. Herrieff. 2, E. Beckwith. 3, Hon. W. Sugden. *Young hen*.—1, D. Combe. 3, J. Hairsine. *Pigmy or Austrian*.—*Cock or Hen*.—1, Cup, and 2, P. Wardle. 3, Dr. J. B. Hicks.

CARRIERS.—*Champion class, for birds that have won more than two Prizes of the value of £1*.—*Black or Dun*.—*Cock or Hen*.—1 and Cup, Capt. H. Heaton. 2, J. Baker. 3, Withheld. *Black*.—*Cock*.—1 and Cup, Capt. H. Heaton. 2, F. Nettlefold. 3, C. G. Cave. *Hen*.—1 and Cup, M. Headley. 2, J. Baker. 3, R. Fulton. *Young cock*.—1 and Cup, E. Walker. 2 and 3, Capt. H. Heaton. *Young hen*.—1 and Cup, Capt. H. Heaton. 2, W. G. Hammock. 3, J. Siddons. *Dun*.—*Cock*.—1, Capt. H. Heaton. 2, F. Cox. 3, M. Hedley. *Hen*.—1, R. Fulton. 2, F. Cox. 3, H. M. Busskin. *Young cock*.—1 and 3, T. Hallam. 2, Capt. H. Heaton. *Young hen*.—1, H. Heritage. 2, J. Brewer. 3, T. Hallam. *Any other colour*.—*Cock or Hen*.—1, T. Hewitt. 2, J. Baker. 3, H. M. Maynard. *Young cock or hen*.—1, C. P. Covington. 2, J. C. Waterhouse. 3, W. G. Hammock. *Any age or colour*.—*Price not to exceed £5 5s*.—*Cock*.—1, C. Cork. 2, F. Cox. 3, H. M. Maynard. *Hen*.—1, H. M. Maynard. 2, G. Kempton. 3, W. G. Hammock.

DRAGOONS.—*Blue*.—*Cock*.—1, J. Wright. 2 and 3, W. Smith. *Hen*.—1 and 2, W. Osmond. 3, W. G. Flanagan. *Silver, black bars*.—*Cock*.—1, W. Osmond. 2, W. Smith. 3, A. McKenzie. *chc*, T. C. Burnell. *Hen*.—Cup and 2, W. Smith. 3, Withheld. *Silver, brown bars*.—*Cock*.—Cup, A. McKenzie. 2 and 3, W. Bishop. *Hen*.—1 and 3, W. Bishop. 2, A. McKenzie. *Yellow*.—*Cock*.—Cup, A. Leith. 2, L. Whitehead. 3, Waterman & Sergeant. *chc*, J. Wright. *Hen*.—1, W. McCandish. 2, J. Wright. 3, G. W. Pratt. *Red*.—*Cock or Hen*.—1, F. P. Ellis. 2, G. W. Pratt. 3, A. McKenzie. *White*.—*Cock*.—1 and 2, W. Bishop. 3, C. Howard. *Hen*.—1, C. Howard. 2 and 3, W. Bishop. *Any other colour*.—*Cock*.—1 and 3, W. Osmond. 2, W. Smith. *chc*, C. Howard. *Hen*.—1, W. Smith. 2, W. Osmond. 3, C. Howard. *Blue or Silver, black bars*.—*Young cock*.—1, W. Smith. 2, J. Lush, jun. 3, J. Albury. *chc*, W. Osmond. *Young hen*.—1, E. C. Young. 2, W. Osmond. 3, T. C. Burnell. *Yellow or Red*.—*Young cock*.—1 and Cup, F. P. Ellis. 2, Waterman & Sergeant. 3, A. McKenzie. *Young hen*.—1 and 2, A. Leith. 3, A. Close. *Silver, brown bars, or any other colour*.—*Young cock*.—1, W. McCandish. 2 and 3, W. Osmond. *Young hen*.—1, J. W. Carn. 2, W. Bishop. 3, Withheld. *Any age or colour*.—*Price not to exceed £4 4s*.—*Cock*.—1, J. Calcutt. 2, S. Turner. 3, F. P. Ellis. *chc*, G. Thickett. *Hen*.—1, G. W. Pratt. 2, C. Howard. 3, S. Turner.

TUMBLERS.—*Almond*.—*Cock*.—1, Cup, and 2, M. Weston. 3, J. Baker. *chc*, T. Hallam, M. Weston. *Hen*.—1, R. Fulton. 2, F. Rayner. 3, J. Baker. *Bald*.—*Cock or Hen*.—1, J. R. Henery. 2, G. A. Poland. 3, Withheld. *Beard*.—*Cock or Hen*.—1 and 2, M. Weston. 3, J. S. Martin. *Any other variety*.—*Cock*.—1 and Cup, E. Beckwith. 2, B. Goodburn. 3, J. Baker. *Hen*.—1, J. M. Braid. 2, G. H. Stevens. 3, M. Weston. *Flying class*.—*Long-faced, any other variety*.—*Single Bird*.—1, C. W. Pileger. 2, S. Salter. 3, T. Matthew.

BARBS.—*Cock*.—1 and 2, J. Baker. 3, R. Fulton. *chc*, W. Larkins. *Hen*.—1, J. Baker. 2, R. Fulton. 3, E. Beckwith. *chc*, E. B. Trotter. *Young cock*.—1 and Cup, W. Larkins. 2, J. Baker. 3, H. Heritage. *Young hen*.—1, J. Baker. 2, W. Fife. 3, M. Hedley.

JACOBS.—*Red*.—*Cock*.—1, 3, and *chc*, S. Salter. 2, H. Heritage. *Hen*.—1, A. G. Shaw. 2, H. Heritage. 3, S. Salter. *Yellow*.—*Cock*.—1, W. Dale. 2, R. Fulton. 3, H. Heritage. *Hen*.—1 and Cup, H. Heritage. 2, W. H. Roberts. 3, S. Salter. *Black*.—*Cock*.—1, H. Jeffery. 2, R. Gibson. 3, S. Salter. *Hen*.—1, W. H. Roberts. 2, Weyman & Buchanan. 3, R. Fulton. *White*.—*Single Bird*.—1, J. Waters. 2 and 3, S. Salter. *Any other colour*.—*Single Bird*.—1, W. H. Roberts. 2, H. Jeffery. 3, H. Heritage.

FANTAILS.—*White*.—*Cock*.—1, Cup, and 2, O. E. Cresswell. 3, J. Baker. *Hen*.—1, J. F. Loversidge. 2, J. Baker. 3, W. Stevenson. *Any other colour*.—*Single Bird*.—1, S. Salter. 2, W. Stevenson.

NUNS.—*Single Bird*.—1, W. Dale. 2, R. Woods. 3, T. L. Johnston.

TRUMPETERS.—*Single Bird*.—1 and 2, J. H. Hutchinson. 3, R. Fulton.

OWLS.—*English, Blue or Powdered Blue*.—*Cock*.—1 and Cup, S. Salter. 2, J. T. Theobald. 3, P. Wardle. *Hen*.—1 and 2, S. Salter. 3, T. H. & A. Stretch. *Young Single Bird*.—1 and Cup, T. H. & A. Stretch. 2, J. Booths. 3, S. Salter. *English, Silver or Powdered Silver*.—*Cock*.—1 and 2, S. Salter. 3, R. Woods. *chc*, F. Thirkell. *Hen*.—1 and 2, S. Salter. 3, W. F. Entwistle. *English, any other colour*.—*Cock or Hen*.—1, 2, and 3, S. Salter. *Young Single Bird*.—1 and 2, S. Salter. 3, E. W. Van Senden. *Foreign*.—*Single Bird*.—1 and Cup, R. Woods. 2, J. Baker. 3, J. T. Theobald.

TURKISHS.—*Blue or Silver*.—*Cock*.—1, R. Fulton. 2, T. P. Carver. 3, J. Baker. *chc*, T. C. Burnell. *Hen*.—1, R. Fulton. 2, S. Salter. 3, Rev. W. F. Lumley. *Young Single Bird*.—Cup, J. Baker. 2, E. Beckwith. 3, H. & G. Heading. *Red or Yellow*.—*Cock*.—1 and Cup, J. Baker. 2, S. Salter. 3, P. A. Parkin. *chc*, J. Baker, J. Dye.

Any other colour.—*Cock*.—1, T. C. Burnell. 2, J. Dye. 3, R. Fulton. *Hen*.—1, C. A. Crafer. 2, O. E. Cresswell. 3, S. Salter. *Young Single Bird*.—1, J. Dye. 2, C. A. Crafer. 3, S. Salter. *chc*, R. & J. Anderson.

FRILLBACKS.—*Single Bird*.—Cup and 2, A. A. Gatty. 3, R. Fulton.

SWALLOWS.—*Single Bird*.—1, F. P. Bulley. 2, J. Long. 3, P. Wardle.

MAGPIES.—*Black*.—*Single Bird*.—1, F. P. Bulley. 2, W. Tedd. 3, A. Stevens. *Red*.—*Single Bird*.—1, F. P. Bulley. 2, W. Tedd. 3, S. Salter. *Any other colour*.—*Single Bird*.—1, S. Salter. 2, F. P. Bulley. 3, W. Tedd.

ARCHANGELS.—*Single Bird*.—1, S. Salter. 2, A. Allen. 3, J. Duffus.

RUNTS.—*Single Bird*.—1, H. Stephens. 2, T. D. Green. 3, J. S. Price. *Young Single Bird, exhibited by the Breeder*.—1, Cup, and 3, T. D. Green. 2, J. S. Price.

ANTWERPS.—*Short-faced*.—*Cock*.—1, J. C. Waterhouse. 2, C. H. Buckland. 3, S. Wade. *Hen*.—1, J. J. Bradley. 2, J. Lister. 3, J. H. Doughty. *Homing, Blue or Blue-checked*.—*Cock*.—1 and Cup, J. M. Chambers. 2, G. Carvill. 3, M. Crust.

Extra.—3, W. Merrifield. A. Wheeler. *Hen*.—1, W. Stevenson. 2, G. Dixon. 3, W. Merrifield. *Homing, and other colour*.—*Cock*.—1, H. Sergeant. 2, E. Wormald. 3, G. J. Lenny. *Extra*.—3, W. H. Cottell. *Hen*.—1, J. Lister. 2, J. H. D. Jenkinson. 3, F. Wuser. *Young cock*.—1, F. A. Key. 2, C. Howard. 3, E. Wormald. *Young hen*.—1, W. Stevenson. 2, J. P. James. 3, G. J. Lenny. *Special Flying classes*.—*Homing*.—*Cock*.—1, W. Merrifield. 2, W. H. Cottell. 3, G. J. Lenny. 4, R. Newman. 5, G. Bowyer. *Hen*.—1, 3, and 5, G. J. Lenny. 2, C. Payne. 4, S. Hutchings.

ANY OTHER VARIETY.—*Single Bird*.—1 and Cup, H. W. Webb. 2, J. Long. 3, J. Baker.

SELLING CLASSES.—*Poster, Carrier, Barb, or Tumbler*.—*Price not to exceed £2*.—*Cock*.—1, J. Guthrie. 2, A. & W. H. Silvester. 3, F. W. Hodson. 4, G. Murphy. *Hen*.—1, R. Woods. 2, J. Leighton. 3, C. Cork. 4, A. & W. H. Silvester. *Any other variety*.—*Price not to exceed £2*.—*Cock*.—1, J. Lush, jun. 2, F. P. Bulley. 3, F. P. Ellis. 4, R. Wood. *Hen*.—1, J. Pyper. 2, E. W. Van Senden. 3, F. P. Bulley. 4, Mrs. A. Dresing. *Pair*.—1, A. A. Gatty. 2, T. C. Burnell. 3, C. Cork. 4, F. P. Bulley. *Homing Antwerps*.—*Price not to exceed £2*.—*Pair*.—1 3, and 4, C. Candler. 2, J. J. Hewitt.

ANY VARIETY, EXCLUSIVE OF CARRIERS, POUTERS, BARBS, OR TUMBLERS.—*Young Pair*.—1, J. A. & M. F. Smith. 2, J. H. Hutchinson. 3, S. Salter.

JUDGES.—*Poultry*: Messrs. T. C. Burnell, J. Dixon, S. Matthew, T. Raines, J. H. Smith, R. Tecbay, and W. B. Tegetmeier. *Pigeons*: Messrs. T. J. Charlton, F. Esquilant, Frank Graham, P. H. Jones, and Jones Percival.

HULL POULTRY SHOW.

THE fifth annual Exhibition of poultry, in connection with the Christmas Fat Cattle Show, opened on Saturday. The prize list is so liberal in some classes that the result is looked forward to with an interest only second to the Palace and Birmingham. We do not quite understand on what principle the schedule is arranged. Game have twelve classes, a £20 champion cup, and six other cups; Brahmas ten classes, with two £10 cups and two £3 cups; Cochins ten classes again, and a couple of cups. Houdans and Hamburgs, Bantams and Waterfowl, are fairly treated, but Dorkings and Spanish have but one miserable class each, and the Crèves La Flèche, Minorcas, Leghorns, Andalusians, *et hoc genus omne*, are altogether omitted. Surely the ways of agricultural shows are inscrutable. However, we must proceed to review the exhibits. The catalogue commenced with twelve classes for *Game*, which produced 132 entries. In Black-breasted Red cocks (fifteen), the winner (Fielding) also deservedly took the £20 cup for best Game cock in the Show. He was a fine powerful bird, of good colour and style, in the pink of condition, and made an easy win of it; second (Foster) was good in quality; third (Pratt) good style, but scarcely fit yet. In Black-breasted Red cockerels (nineteen) the winner (Lyon) was a big, reachy chicken, fine in feather; second (Harley), splendid in head, but rather long in body; third (Jeffries), not up to the other two, but still a good bird. Brown-breasted Red cocks, twelve entries. The first (Ashburner), second (Sowerbotts), and third (Matthew) stood out prominently from the rest of the class; all three were good lemon-pencilled birds with dark face and eye. In cockerels (eleven), first (Braithwaite) was a splendid-headed bird, scarcely big enough; second (Mercer) a good one of the proper stamp; third (Ashburner) was good in colour, but rather heavy behind. In the Any other variety cock class nine birds came forward. The first (Walker) also took the cup for Any other variety male bird. He was a yellow-legged Pile, very large and perhaps a trifle heavy-looking; second (Matthew) was a very pretty Duckwing, rather too heavy in feather; third (Sales) a Duckwing again. The superiority of feather in the Piles no doubt gained them the majority of the prizes. In any other variety cockerel (eight) Piles were again to the front; first (Knowles) being a fine slashing chicken not quite clear in white or perfect in marking, as he had a few red feathers in breast; second (Whitaker) a Pile also with a white stripe in hackle and good colour, but behind the winner in make; third (Jamieson) a willow-legged one of fair quality. Black Red hens (twelve).—First (Adams) a well-shaped one, good in head; second (Stavely) tall and very good in colour; third (Robertshaw) a tall shapely hen rather straky in feather. Black-breasted Red pullets (fourteen).—First and cup (Lyon) a beautiful bird in all points, but rather inclined to be small in size; second (Dutton) larger, but not quite equal to the winner in colour; third (Goodwin) a nice pullet. Brown-breasted Red hens (twelve).—First (Matthew) also took the cup for Brown Red hen or pullet. She was a powerful hen, fine in shape and colour; second (Dyson) a very good dark-breasted one; third (Ward) nicely pencilled on breast. Pullets, a strong class of seventeen.—First (Warner) fine in feather and long in head; second (Ward) very close on to the winner; third (Braithwaite) pretty but small. Game hen Any other variety (four).—First and cup (Harley) a willow-legged Pile, faulty in comb, on which account we preferred second (Holmes), a pretty Duckwing well shown; third (Cameron) a nice Duckwing, rather too red on wing. Pullets (thirteen).—First (Dyson) a yellow-legged Pile, good in all points, very dark on breast; second (Staveley) a small but shapely Duckwing; third (Matthew) a Duckwing again, failing a little in colour.

Brahmas with eight classes and a liberal prize list were not as a

whole nearly up to the Palace quality. In Dark cocks (seventeen) first (Mitchell) was of good size, fair shape, and nice in comb. He had heavy hocks and was rather hollow in breast. Second (Cotes) nice in shape, good foot feather without hock, slightly mottled on breast and not fine enough in comb. Third (Kendrick) white in tail, deficient in breast, and heavily hocked. 332 (Comyns) very highly commended, good in head, perfect in comb, but heavily hocked and saddle not up yet. Dark cockerels (sixteen).—First and cup (Mitchell) we did not like. He was hocked, lumpy in appearance, deficient in saddle, and rather grizzled in colour; he was nice in head and comb. Second (Lingwood) coarse in comb and rounded in saddle, broad and large at stern, but too much down by the head. Third (Sowerby) a poor one, too high in tail, straight in back, and slipped in wing. In Mr. Comyns' two very highly commendeds we recognised the Palace sixth and very highly commended; they had hard luck here. Light cocks (eleven).—First and cup (Percival), though heavily hocked and rough in comb, won easily by size, shape, and colour. Second (G. H. Wood) fine in shape but very meaty in comb, and warm in colour on saddle. Third (Morgan) we have no note of except so far as he may be included in the general comment "a poor class." Cockerels.—First (Devonport) good in size, shape, and leg feather, but not quite clear in colour or straight in comb. Second (G. H. Wood) and third (Haines) nicely shaped hocked birds of fair size. Very highly commended (Lucas) a very stylish one, but hollow in breast. Dark Brahma hens (sixteen).—First and cup (J. Wood) a well-known hen hardly moulted through yet. Second (Percival) nice in marking but cochiny in cushion. Third (Sowerby) we did not like, as she was very rough and poor in colour. 401 (Holland) commended, large, shapely, and well-marked in the dense style, but heavy in head and brown in ground. Pullets (fifteen).—First (Percival) a mere weed, streaky in colour, and hardly a Brahma point about her. Second (Roebuck) far too long in back and indistinct in marking. Third (Comyns) nice shape and beautifully pencilled breast, but too young—our choice in a poor class. 410 (Lingwood) a good large pullet with a defective eye. 414 (Norris) very highly commended, large and beautifully pencilled, but utterly deficient in foot feather. Light hens (eleven).—First and cup (G. H. Wood) lowest on leg and best in shape, but very dirty; on this account we should have put her behind second (Mitchell), whose chief fault was a Cochinchin cushion. Third (Norris) large, but carrying too much head for a pullet, also too much tail.

Cochins, especially in the Buff classes, contained some birds we have seldom seen equalled. Buff cocks were fourteen in number. The winner (Hind) was grand in size and shape, and even in colour—in fact, a clinker, moderate hocks his only fault. Second (Weeks) another grand bird, but not quite so large, and rather coarser in comb. Third (Brown) very square in body, but rough in comb and slipped in wing—a strong class. Cockerels (twenty-four).—First (Pye) a shapely Cinnamon, good in all points. Second (Brown) large, but not so even in colour and a trifle hollow in breast. Third (Sear) smaller, but well made, streaky, however, in saddle. Partridge cocks (eleven).—First (Tudman) also took the £10 cup; he was a good-sized richly-coloured bird of true Cochinchin type. Second (Percival) the Palace winner we thought, still deficient in saddle. Cockerels.—First (Morgan) smart in shape and rich in colour, but carries too much tail. Second (Cannan) fair size and shape, but dull in colour. The light was bad when we were at this class, but unless he had some blemish undiscovered by us, very highly commended (G. H. Wood), good in all points, was a long way ahead of the winners. Buff hens (fifteen).—First and cup (Brown) a rare good one in size, shape, cushion, and feather, and very fair in colour, worth the journey to see her. Second (Pattinson) another good one, but long in leg and poor in colour after first. Third (Sowerby) a nicely-shaped lemon, not quite clear on cushion. We thought all three winners remarkable birds for any show, and the class a very strong one. Pullets (twenty-two).—First (Paxon), and second (Percival) were both too high in tail for our taste. Third (Brown); 565 (Brown) and 518 (Rigg) highly commended, were our pick out of the class. Partridge hens (eight).—First (Brown), good size and fair shape and markings. Second (Dorrington) smaller but very true in shape and well marked. 588 (Southern) very highly commended, a very well-marked one of the dark type, but wry-tailed. Pullets.—First (Tudman) a moderately marked bird with a frosted comb. Second (Rutledge) a mistake, a poor bird with no marking, inferior to 598 (Southern) highly commended, a well-marked one, and indeed to several others. Whites won both prizes in the Other variety. Old Cochinchin class (four).—First (Badger) were a fairly good all-round pair. Second (Percival) cock defective in colour on shoulder. In chickens (seven) Whites were again to the front. First (Badger), and second (Darby) being fair birds but not up to Palace form.

Spanish.—One class, two entries. First and special (Dixon) fine birds, large in face but wanting care; second (Bowlton) moderate.

Dorkings.—One class only again (eight), were poor. First (Cannan) were moderate Darks; second (Cranston) fair Silver-Greys.

Malays brought out eight moderate pens. First (Blake) hardly upstanding enough, but otherwise good; second (Richards) moderate in quality.

Houdans.—Here the classes expanded again into four. In cocks (five) the winner (Irving), who also took the Houdan cup, was a large-bodied bird, good in crest but only moderate in comb. Second (Thomas) nice in colour, but rather slight for an old bird. Cockerels (nineteen, with Mr. Beedham's four pens empty) were a moderate class. First (Coppstone) nice shape and colour, moderate in crest, very defective

fifth toe on right foot. Second (Thomas) squarer in body and better in foot and crest—our choice for first. Hens (ten).—First (Meredith) a square-shaped bird of good colour, best in crest and muffling; second (Thomas) nice in colour again. Pullets (twelve).—First (Lane) very neat in comb, crest, and muffling; second (Beldon) long in body, nicely marked, and good in comb. 686 (Millner), very highly commended, a squarely built pullet of the dark sort.

Hamburgs.—Black cocks of any age (twelve).—First (Bentley) very smart in head and bright in colour; second (Beldon) beautiful in colour but not so good in head. Golden-spangled cocks, any age (eight).—First and sectional cup (Rawnsley) a capital bird, good in comb, carlobes, and colour; second (Duckworth) a similar stamp, pressing closely on the winner. Silver-spangled cocks, any age (seven).—First (Beldon) the Crystal Palace winner again to the front; second (Rawnsley) a new one from the same yard as the Palace second, but again failing to lower the colours of the winner. Golden-pencilled cocks, any age (ten).—First (Beldon) Crystal Palace winner, also closely pressed by second (Kidson). Silver-pencilled cocks, any age (five).—First (Beldon) seemed to us very like the third at Palace; second (Rawnsley) a fresh one well shown. Black hens, any age (nine).—First (Cannan) good in colour, nice in earlobe and comb; second (Winn) a similar stamp, close up to the first. Golden-spangled hens, any age (eight).—First (Duckworth) and second (Cartwright and Butterworth) were rightly placed over the Palace winners. Silver-spangled hens, any age (eleven).—First (Beldon) the Palace winner, looking well; second (Cannan) a fine old hen, not so good in colour as the first. Golden-pencilled hens, any age (eight).—First (Webster) a very nicely pencilled bird of good colour; second (Beldon) another very good one, like the Palace second. Silver-spangled hens, any age (six).—First (Rawnsley) a new one, very fine in head; second (Beldon) the Palace winner fairly beaten here.

Game Bantams (nine).—First (Firth) a fair pen of Piles; second (Hore) moderate Black Reds; third (Swift). Any other variety Bantams (twelve).—First (Rawnsley) Black Rosecombs, very good but rather large; second (Bamford) good gold-laced; third (Charlton) nice Blacks, smaller than first but coarser in head.

Any Other Variety of Fowl.—First (Beldon) good Silver Polands; second (Partington) Goldens; third (Cannan) Silvers again. We append the prize list of the Ducks, Geese, and Pigeons, which time did not permit us to criticise in detail. Mr. Lane judged the Game and Bantams, Mr. Teebay the Brahmans, Mr. Dixon the Cochins, while the remaining poultry classes were divided between the last two gentlemen. Mr. Jones took the Pigeons.

GESE.—*Gander and Goose*.—1, F. G. S. Rawson. 2, R. Dodsworth *etc*, G. V. Snell, W. H. Garforth.

DUCKS.—*Duck and Drake, Aylesbury*.—1, and Cup, W. Weston. 2, J. Hedges. 3, Mrs. Gunn. *Rouen*.—1, G. V. Snell. 2, J. Newton. 3, F. G. S. Rawson. *Any other variety*.—1, W. Bygott. 2, T. P. Carver. 3, Mrs. Gunn.

PIGEONS.

CARRIER.—*Black or Blue*.—1 and 2, J. Baker. 3, G. V. Cave. *Carrier any other colour*.—1 and 2, J. Baker. 3, R. Woods. *Carrier, any colour, hatched in 1880*.—1, H. Adams.

POUTER.—*Black or Blue*.—Cup and 2, J. Baker. 3, F. Stamford. *etc*, J. Guthrie, J. Hairsine. *White*.—1, R. Kirby. 2, A. Spencer. 3 and *etc*, J. Baker. *etc*, A. J. Mays. *Any other colour*.—1, J. J. Fowler. 2 and 3, J. Hairsine. *etc*, J. Baker.

TUMBLERS.—*Short-faced*.—1 and 2, J. Baker. 3, R. P. Moon. *Long-faced*.—1, 2 and 3, R. Woods.

BIRMINGHAM CATTLE AND POULTRY SHOW.

THE preparations for the thirty-second annual Exhibition of fat cattle, sheep, pigs, eorn, roots, poultry, and implements of husbandry, &c., at Bingley Hall, are being carried on with great spirit, and will be completed in time for the opening, which takes place on Saturday the 27th inst.

The sum of £2700 will be awarded in prizes in the various departments, and the entries throughout are such as to warrant the conclusion that keen competitions will take place in most of the classes before the Judges can declare the winners.

The cattle, though not quite so numerous as last year, in consequence of the classes for aged oxen being omitted, will in point of merit fully make up the deficiency in numbers, for they come from exhibitors who have previously carried away the highest honours of the Show, and others well known for the splendid stock they exhibit.

Sheep will be a fair show, and pigs will be more numerous than last year.

The entry of roots is the largest ever made, and it has been found that the entire front of the galleries, round which the roots

are displayed, will not be sufficient to hold the whole of them ; and extra stages will be erected against the wall of the gallery on the south-west side of the first-class refreshment room.

The poultry and Pigeons entered amount to 3062 pens. These will occupy their old position in the gymnasium and also nearly the whole of the bay adjoining the implement department. The whole of the pens will be galvanised wire, similar to those in use last year, which gave such satisfaction, being so much lighter than the old pens.

The demand for stand space has been as great as ever, and the Committee have been compelled to allot to exhibitors in several sections much smaller spaces than they applied for. Amongst the implement exhibitors are nearly all the leading firms in the kingdom, who will have on view some of the latest and best improvements in the various articles they show.

H.R.H. the Prince of Wales has entered cattle and sheep, and the following also contribute to the Show :—The Duke of Buckingham, Lord Chesham, Earl of Dartmouth, the Earl of Ellesmere, Viscount Falmouth, Earl of Gainsborough, Earl of Harrington, Duke of Sutherland, Lord Tredegar, Lord Walsingham, Duke of Wellington, Earl of Zetland, Sir John Swinburne, Bart., &c.

The railway companies will run excursion trains from all parts at reduced fares ; and in addition to the ordinary arrangements in this direction, the London and North-Western Railway Company have announced that they will run an eight-day excursion from Swansea and South Wales district, and excursions from Peterborough and Stamford.

The increase in the entries has necessitated the appointment of additional Judges, and Mr. T. C. Burnell has consented to act in the poultry department, and Mr. Jones Percival in that for Pigeons.

The following is a statement of the classes allotted to each Judge :—

POULTRY.—Mr. T. C. Burnell: Creve Cœurs, Houdans, Spanish, Andalusians, Leghorns, Minorcas, Sultans, variety classes of fowls and Bantams, and selling classes. Mr. James Dixon: Polish, Hamburgh, Ducks, Geese, and Turkeys. Mr. W. R. Lane: All Game except Black Reds, and all Game Bantams. Mr. M. Leno: Light Brahmas, Dorkings, Fancy Ducks, and Fancy Bantams. Mr. J. H. Smith: Black Red Game and Malay. Mr. R. Teebay: Dark Brahmas, Cochins, and Langshans.

PIGEONS.—Mr. T. J. Charlton: Pouters and Antwerps. Mr. H. Child: Muffed and Long-faced Tumblers and Dragoons. Mr. Esquilant: Fantails, Nuns, Swallows, Magpies, Jacobins, Turbits, Owls, Short-billed Frilled varieties, and new varieties. Mr. Jones Percival: Carriers, Short-faced Tumblers, Barbs, Trumpeters, Runts, Archangels, and the selling classes.

THE POULTRY CLUB.

A LARGE and influential meeting was held at the Crystal Palace on the Tuesday in last week. Most of the resolutions which we printed a fortnight since were passed, the only important variations being that the addition of seven new members to the Committee was resolved upon, and the resolution as to hiring a club room in London negatived. It was announced that Messrs. L. Wright, Teebay, Dixon, and Tegetmeier had been elected honorary life members of the Club, and that several new ordinary members and associates had been elected. We were glad to see so good a meeting, and so intelligent and keen an interest displayed in the questions under discussion. The meeting lasted nearly two hours, as there was much business to get through. We trust that such of our readers as are interested in our poultry department and are not members of the Club will consider the propriety of joining it. The Club was founded to promote honesty and fair dealing in the poultry world, and it commends itself to the notice of every honest fancier.

VARIETIES.

WE have made arrangements for the insertion in our next issue of a full report of the Birmingham Poultry Show. We hope also to give a report of the Pigeons. As the Journal is in the hands of our readers on Thursday morning, they will have an opportunity of going through the classes with our report in hand. We shall arrange for an extra large supply of the Journal to be sent to Birmingham, so that there may be no difficulty in obtaining copies.

— **BIRMINGHAM POULTRY SHOW.**—We are requested to state that the whole of the arrangements for feeding and penning the birds at the forthcoming great Birmingham Poultry Show have been entrusted to "Spratts Patent," of Bermondsey, London, who will at

their stand in Birmingham Cattle Show exhibit samples of their latest novelty, a "Patent Malted Cattle Food." This firm have also received the order to feed the dogs at the coming Birmingham National Dog Show on their Patent Meat "Fibrine" Dog Cakes.

— **THE DUBLIN POULTRY AND PIGEON SHOW AND BELFAST SCHEDULE.**—We regret to hear that the proposed Show in Dublin has fallen through. We fear the Dublin men are too ambitious in their efforts. Nothing less than a grand show will satisfy them. Belfast holds a good Show each December on moderate lines, with an increasing prize list and increasing success each year. The schedule for this year's Show, to be held December 15th and 16th, is before us. There are forty-two classes for poultry and thirty-seven for Pigeons, with prizes of £1, 10s., and 5s., entry 3s. 6d.; and fifteen classes for cage birds, with prizes of 12s., 6s., and 4s., entry 1s. 6d. There are besides fourteen poultry, nine Pigeon, and one cage-bird cups or special prizes. This is a great advance on last year's schedule, and we trust a good Show will be forthcoming.

— **SHOULD WE SHOE OUR HORSES?**—Nearly every owner of a horse, nearly every groom and every stableman, will laugh at the question. Messrs. Longmans, however, have published a volume by "FREE LANCE," the object of which is to prove that the heavy horse shoe of the present day is parent to all the ills that horseflesh is heir to. "FREE LANCE" believes that no shoes at all are necessary. He has the benefit of a wide experience, which proves that shoes on the Charlier system are quite sufficient. This is simply a little band of hard iron, 5 ounces weight, let into the tip of the foot. Messrs. John Smithers of London have a large stable. They find that with the Charlier tip the horses have a surer footing, go better, are healthier—being free from diseases of the foot—work easier at a greater age, and are altogether cheaper to keep in health, and last longer than when they adopted the old customary system.

— **HOW TO MAKE FLOUR.**—The National Association of British and Irish Millers, whose offices are at 61, Mark Lane, having regard to the active competition which is now going on between Austro-Hungary, America, and England in the endeavour to produce the finest and whitest flour for bread-making, has resolved on the 10th of May next and four following days to show all the different processes of making flour at work in the Agricultural Hall. It is expected that the exhibition of the many strange varieties of machinery from all parts of the world will prove of great interest and value ; but in the meantime the Council of the Association wish it to be known that any suggestion or information will be thankfully received.

ENGLISH v. FOREIGN HONEY.

ENGLISH bee-keepers have the satisfaction of knowing that their honey is unsurpassed for excellence and flavour by the products of any other country. By English honey I mean the honey of the United Kingdom, for the honey of Ireland and Scotland is equal in quality and flavour to that of England. It is rather remarkable that I have never found one sample of foreign honey equal in flavour to ours. For years I have considered that the Chilian honey offered for sale in England is better than that of France, Spain, and Portugal—better, too, than African and Australian honey. Swiss honey is said to be excellent, but it has not been my fortune ever to taste it. Doubtless the differences of flavour in honey are traceable to the plants from which it is gathered ; but the quality of honey may be injured in taking it from the combs, and it may be spoiled by adulteration. One thing is evident—that the great bulk of foreign honey in the English market is as inferior to good English honey as foreign Grapes are to good English Grapes. The cause of this in the case of the Grapes is easily understood and explained, but with honey the reason is not so evident. Even the Narbonne honey of France, which has long been lauded as excellent, is far inferior in flavour to good English honey.

Two or three months ago a Manchester merchant who does some business with a house in Palermo (in Southern Italy), had four jars of honey from the Botanical Gardens of Palermo. Being unable to sell it he brought a sample here with the hope that I would tell him how and where it could be sold. Though quite different in flavour from English honey, being deficient in richness, it was very good. I took the gentleman with his sample to a chemist of our town, who bought 100 lbs. of the Palermo honey at

117. per lb. The gentleman sold 50 lbs. more to an Italian warehouse in Manchester, and sent the other jar to me; it was speedily sold as honey from Palermo Botanical Gardens. This consignment was called the first crop at the Gardens, and a second crop of 1000 lbs. was predicted and expected. Well, the second crop has been reaped, the half of which—viz., 500 lbs., arrived in Manchester on the 5th of this month. A sample was brought here for examination, the aroma of which was not quite so fine as that of the first crop. This made me think about the first crop of tea leaves being the best, and why the first blossoms yielded honey the most aromatic. I thought, too, of what an inviting place Palermo or Southern Italy is for bee-keeping, with its blue skies, warm climate, long summers, and rich pasture. If bees in Scotland properly managed can store 50 and 60 lbs. in a month on the moors, what would they not do amongst the Orange groves of Palermo?—A. PETTIGREW.

BAR-FRAME HIVES.

I AM a very young hand at bee-keeping, with slight pretensions to scientific handling. I have kept them for many years, sometimes getting a little honey—destroying the bees—but oftener obtaining nothing. A year or two ago they died out entirely. In the autumn of 1879 I was aided by a bee friend. The result was that our local carpenter made me three combination hives (Abbott's), and that my friend and I drove several stocks of bees "in very reduced circumstances," and I fed away, and had thus my three hives peopled, each having about six bars. To one at the third attempt I succeeded in getting a Ligurian queen accepted, and the early part of 1880 season it did well; but, as Mr. Pettigrew remarks, they, the workers, encased her at the onset with evil intent, and she was not accepted without damage—her wings were injured. This, it seemed to me, affected her well-being in the middle of the season, and by my bungling I lost her, so that this hive did not do anything like what it might have done, or what the two others did. In one of the others I found early in the spring a weakened hive and a damaged queen, and soon she was turned out dead. The remains, very small, I added to the Ligurian hive. To replace this I bought from my friend in March one of his well-stocked hives with a hybrid Ligurian at its head; this hive was very strong, so I started the year still with my three stocks in combination hives. I must preface my results by stating that we are not here in a very grand honey country; probably I have done better than I otherwise should because so many bees died the previous year—1879, scarcely any person having saved bees who did not tend them very carefully.

The hive bought from my friend swarmed on the 20th May—a monstrous swarm that filled a straw skep in which they were taken. They were placed in a box holding nine bars, and in spite of a large super capable of holding 25 lbs. of honey being given them I had two swarms from them, both large. The hybrid hive sent out a second swarm on the 30th May, a pouring wet afternoon; and the swarm not being expected was left exposed, taken unsatisfactorily, syruiped, and added to another stock. The 4th June saw yet another large swarm issue from this hybrid hive. Had I been more *au fait* with them I should have returned them to the hive and destroyed any other queens; but the fact was that these bees were decidedly extra cantankerous, disdaining the soothing influences of tobacco, and making it decidedly hot work for those who manipulated the hive, and I feel convinced that from them I have not obtained comparatively the same amount of honey. The other hive sent off two swarms; in the second, after hiving I found a few bees on the board, and looking closer found it was the queen (as I thought) rather weak. She was placed inside the hive, and the following morning two dead queens were outside, so that there must have been three in the swarm.

By driving and uniting I reduced my stocks in September to four for the winter—as many as I could conveniently manage; and beginning with three stocks, I have taken over 197 lbs. of clear drawn honey, nearly 50 lbs. of which was super honey. I am quite aware that this is nothing to some persons, but here I have no Heather harvest, and with the Limes the chief source of supply is finished, and considering my ignorance and great want of experience I think I have done wonders.

Besides the honey, however, I have about a score of bars more or less filled with worker comb from which the honey has been removed by the extractor. Most of these have been made or started on the artificial comb foundation. Neither have I with care had much difficulty with this. I have ordered the carpenter in making the bar frames to run a narrow groove on the lower surface of the top of the bar; into this I slip the comb foundation carefully cut to size as to the width, and then I fill this groove with the melted wax; a drop to fasten the sides completes the

business, and with me the bees have taken to it at once.—Y. B. A. Z.

OUR LETTER BOX.

Bees Deserting Hive (*Constant Reader*).—The desertion of a hive under the circumstances you describe is very difficult of explanation. It would probably rest in some dissatisfaction with the hive itself; and if the box weighing "nearly 50 lbs." was a single one, it must have been little less than a block of sealed store, and most unfit for winter quarters. The bees have in all likelihood united themselves to some other of your stocks, for this is the habit of absconding parties. Great weakness and queenlessness will sometimes lead to the result you give.

Draining Comb (*Constant Reader*).—The honey from store combs can be very expeditiously obtained with no injury to itself, or, to speak more correctly, with less injury than is caused by the dust, exposure, and delay involved in draining, by placing it (care being taken that no pollen is present) in a vessel, (earthenware preferred), which is in turn placed over a saucepan boiling on the fire, or into a copper. The wax melts and rises, and may be removed after cooling, as fat is taken from broth. Should the honey be rendered cloudy by the presence of undiscovered pollen, the former must be placed in a warm position—a kitchen by example—for a month or two, when the pollen will subside. The honey may then be drawn off by a syphon, and the thick remainder, after being thinned with water, will make good feeding stuff if due care be taken to prevent robbing. With combs in which brood has been raised the plan is quite inadmissible, and the extractor gives the only good means of getting the honey. Failing this, draining is the best course, but in this a comparatively high temperature much quickens the process.

REMARKS.

- 14th.—High wind and rain in morning; stormy afternoon, with gleams of sunshine; rain again in evening.
15th.—Fair morning; dark at 11 A.M.; rain commenced 11.30 A.M., heavy during the afternoon, slight in evening.
16th.—Very stormy day, high wind and heavy showers, occasional flashes of sunshine; bright moonlight night. At 2.30 P.M. barometric pressure only 28.695 inches.
17th.—Fine, bright, colder day; clear moonlight night.
18th.—Cold foggy morning; snow at 2.15 P.M.; latter part of the day wild and stormy, with rain and snow.
19th.—Early morning dull; fine, bright, and cold rest of the day.
20th.—Very fine, with bright sunshine; latter part of afternoon hazy; clear in evening.

Great oscillations of barometer, and considerable range of temperature, the night between 13th and 14th being excessively warm (not below 54°), while there were sharp frosts on three other nights.—G. J. SYMONS.

COVENT GARDEN MARKET.—NOVEMBER 24.

OUR market is now very bare of home-grown fruit, American goods monopolising the trade, though samples as a rule are reaching us in bad condition and making low prices, while sound parcels are in request at improved rates. Trade quiet.

FORCING FIGS IN POTS.

PRACTICAL horticulturists have hitherto done very creditable work in bringing almost every available fruit capable of being forced, into popularity for the dessert, but somehow the luscious Fig has not had the same attention devoted to it, nor been brought with rapid strides into daily use. The Fig appears to be regarded as an aristocratic fruit, for the number of dishes of forced Figs shown at our first-class exhibitions is generally very small in comparison with other kinds of fruit, and we are led naturally to ask why that should be so. It cannot be, I think, because gardeners are reluctant to place the matter before their employers, since a man who takes a pride in forcing Grapes would also be equally able and willing to force Figs; neither can it arise from any great difficulty in cultivation, nor from the expense attached to the work, for where Vines can be forced Fig trees can be forced also at the same time and in the same house. On reflection I have thought, that as the Fig is a very ancient fruit, and its wants in the matter of forcing have been lucidly handed down to us by former generations of gardeners when there were not half the conveniences for forcing that there are now, there can be no special liking for the fruit in this country, or it would be more extensively grown. However, the fact remains that Figs have not obtained any prominent position on the dessert table. I find from what I have read that gardeners fifty or a hundred years ago took great pains to bring the Fig to perfection out of doors, and their ideas of forcing the trees in heated structures were much in advance of the means at their command for doing it. Now there is no lack of suitable houses for forcing the fruit, and I think an effort should be made to bring it more frequently into use, and with that object in view I will give my plan of forcing Fig trees. I am aware it is not new, but I have in every instance proved it a good and successful one, and hence it is worthy of record in the Journal.

Those who intend forcing a few trees should purchase some of medium size—say of two or three years' growth in pots, not those planted out. They will at this time of the year have several bearing shoots, and ought to be compact well-grown plants with the pots full of roots. If the plants or miniature trees are grown on a stem rising a foot from the pot before branching out so much the better, as then they will not be liable to throw up suckers, which ought always to be prevented after the trees are well formed. Next turn them out of the pots and cut quite two-thirds of their roots off. I used to cut

them off with a chopper. After this pot the trees in some rich soil similar to that used for Cucumbers, and press it into the pots as firmly as possible to within 2 inches of the rims, then wash the trees the same as Vines are washed, or paint them with a mixture that is used for Vines. Water the roots and place the trees under temporary protection until the forcing house is ready.

Figs thrive well in gentle bottom heat, and this should be prepared for them either in a house to themselves or in a pit in the vinery. This bed is made up of farmyard manure and leaves prepared as if for Cucumbers. After the heat has declined sufficiently the pots must be plunged up to the rims; but it will be safer if they are previously placed upon the bed, afterwards half plunged, and then finally plunged. Although Fig trees are not quite so easily started into growth as Vines are, they succeed admirably in the same house; therefore I need not describe their treatment in detail, it will be sufficient to state that the trees must be frequently syringed and watered at the roots. The pots soon become full of roots, and, indeed, so vigorously do the roots move that they are soon through the bottom of the pots and running into the bed of manure. When that is found to be the case the bed must be watered occasionally, and at this stage the soil in the pots must never be allowed to become dry; in fact, from this time the whole crop is dependent upon a plentiful supply of water, with liquid manure three times a week. Top-dressing, too, must be done as soon as necessary, as the Fig is a gross feeder, and the means of sustenance must be liberally and promptly supplied. As the Vines advance so will the Figs, but by becoming root-bound so soon their growth is not too vigorous, but just of that medium character so necessary to fruitfulness; however, some of the shoots will need the points pinched out when the fruit is swelling-off before ripening.

If the trees are started in December with the Vines, the Figs will be ripe at the latter end of May or the beginning of June. The trees should be allowed to remain in the house and ripen their wood in the same way as the Vines. The leaves will gradually turn yellow and drop off before those of the Vines; the trees may be taken out of the bed and plunged in the open ground until the autumn, then to be afforded protection in a cool dry shed until they are wanted again for forcing. If the trees are taken proper care of most of the embryo fruits on the current growth will remain on, and will produce the first crop the following year, and the second crop will be advancing while the first crop is ripening. This second crop will prove the larger as well as the better crop of the two.

By the above method of culture the Figs come much finer and of better flavour, and at the same time are more numerous than if the trees are started into growth with their pots full of roots as some advise, for it is the roots that must have the first and the best attention.—THOMAS RECORD.

FANCY PANSIES.—No. 2.

SEVERAL kind letters from authorities on Pansies have reached me since No. 1 (p. 435) appeared, corroborating all I advanced in support of the proposition that the Fancy varieties are rapidly supplanting the shows. One friend, the Secretary of the Scottish Pansy Society, says, "I am glad you are writing about the Fancy Pansies, as that class has quite eclipsed the Shows, not only with

the general public but with real old Pansy growers." The schedule of the Society's Show in June last fully bears out this view, advanced as it may appear, when not fewer than thirty prizes were offered wholly or in part for Fancies. And this revolution having taken place "o'er the border," where Pansies are more highly esteemed and more extensively raised and grown than anywhere else in the kingdom, it is not surprising that the advanced party has adherents everywhere where the flower has admirers. Given, then, that Fancy Pansies have with surprising rapidity come to the front, I may with grace say more concerning their merits and demerits.

The wealth of favouritism now accorded to them has produced the customary evil—too many new varieties are sent out, many of which either so closely resemble some already in cultivation as to seriously lack distinctiveness, or are deficient in that all-important quality, harmony of colour. It is very annoying when one has paid about 5s. for a new variety to discover that the illustrious stranger is so nearly like an old one that the two blooms have to be minutely examined to discover the difference, and when discovered to be obliged to conclude that the difference is in favour of the old one, or is so trifling that the two cannot be staged together. Upon this point I cannot too strongly insist, not only to prevent disappointment to the purchaser, but for the sake of the reputation of the raiser. In writing upon this subject in your columns in February, 1877, I said, "I would rather send out one really good flower in five years than annually put upon the market a dozen or two of mediocre merit, to the injury of my own reputation and the discouragement of those desirous of keeping pace with the times." Since that time I have not found any reason to alter the opinion; on the contrary, it has been strengthened with the blooming of every batch of new flowers. Indeed I have come to the conclusion that it would be well for all new Pansies to pass an examination for a certificate before they are recognised as qualified to rank as additions to the already too numerous Pansy family. Surely there are enough lovers of the flower to start an English Pansy Society, and the formulation of rules and the fixing of a standard are matters of detail in which our Scotch friends would gladly render valuable assistance. That the conditions are ripe for the formation of such an association cannot be contested; the flower is popular and the number of growers daily increasing; new varieties are being raised in profusion and are eagerly bought. Under the protection of such a society no schedule would be long without a Pansy class, and then what an honourable rivalry for its certificates and medals! I can imagine a great international show, England v. Scotland, and the former defeated, but I can also imagine our canny neighbours teaching us how to defeat them. May I live long enough to see these imaginings become solid facts.

Returning to the point where this digression began, it may be asked what amateurs are to do if they may not depend upon the new varieties being distinct and improvements upon the old. I can only tell them the method I have found to answer best. Write out a list of those you have, and decide how much you will spend; then place yourself in the hands of a florist who has made Pansies a speciality for years, and ask him to send as many distinct and really good varieties as he can afford for the money. Depend upon it you will be well treated. Specialists have a healthy sympathy with those who show an inclination to favour their hobby, and the catalogue price is no criterion of the exchange you will receive for your money. I am bound to add here that this opinion has been formed chiefly from transactions with the great northern growers, notably Messrs. Dicksons & Co., and Downie & Laird, Edinburgh; W. Paul, Paisley; and Cocker & Sons, Aberdeen; though I have had nothing to complain of as regards quantity from midland and southern raisers.

Thus far I have (to my own satisfaction, at any rate) proved that Fancy Pansies are in increasing favour, shown that their popularity is attended by an evil that is to a great extent remediable, suggested a national recognition of their merits in the remedy, and given a recipe by which that evil may be largely avoided. Be it mine, then, in a third communication to enumerate the varieties of this charming family that attain most nearly the standard of excellence.—M. H. MILLER, *Leek*.

VEGETABLE ROOTS FOR FORCING.

We cut our first forced Asparagus a fortnight ago; Rhubarb and Seakale will soon be ready; but I do not suppose many of your readers begin operations of this kind quite so early, so that a few notes on the subject will still be in time to be useful. Strong well-matured roots are the only kind worth attention at this season, and unless these can be had the crop will hardly pay for the labour, and little else than disappointment need be expected.

As a rule when roots are lifted for forcing they are not intended to be used again, or at least no crop in the ordinary course is expected from them until a year or two afterwards; and this evidently leads many to think, especially when the roots are intended to be thrown away after forcing, that it does not matter how they are taken up and cut so long as the crowns are only left to sprout. But it does matter, and that considerably. Let the roots be all alike good; cut and break one half of them, and be particular to keep the other half whole and uninjured, then place them all in to force together, and it will soon be seen which plan gives the best results. Those lifted carefully will afford produce some days or weeks before the other section, and both quality and quantity will be more superior in the one case than the other. This is particularly the case with Asparagus and Rhubarb; and the not unusual way of halving the roots of the latter, taking one part in to force and leaving the other to form a crop in the ground, is a mistake. Two or three good roots of anything will give more satisfaction than a crowd of ends and parings. Seakale bears ill treatment better, but it, too, should be handled carefully.

It is not necessary to enter fully into the particulars of forcing these roots, as good and practical details are often given respecting them in the weekly calendar of garden work; but I may remark that with a little heat and moisture, in either glass house or shed, anyone may easily have a supply of such vegetables as those named, and with a little care the produce will stand a good chance of coming early, excellent, and plentiful.—J. MUIR.

NEW FRENCH ROSES.

THE first instalment of announcements of new Roses has reached us, but it does not excite the flutter of excitement amongst us on this side of the Channel that it did some twenty or thirty years ago. We have learned to distrust the magnificent descriptions with which they are heralded. We have discounted the terms "magnifique," "superbe," "hors ligne," and such other high-sounding adjectives. We do not particularly care to know how many leaves there are on a branch, or whether the wood is spiny; and although we do have a grand fish now and then, the quantity of useless ones we have to throw away far outnumbers them. If out of some sixty or seventy varieties we can manage to find three or four good ones we are happy. Besides, we are getting such good Roses from our English raisers, and we have so many good opportunities of seeing them before they are let out, that we prefer waiting a bit until the French Roses are a little more known before acceding to the flattering accounts given of them by their fond parents, who are too often blind to the defects of their offspring.

The nomenclature is more absurd than ever. We have had heaps of Souvenirs, and if the Rose is good we have no objection to remember the persons whom they commemorate; but we have now got a step further. Hold your breath, ye Rose-growers of England, while I announce to you a new Rose with the following sweet little name—"Fiançailles de la Princesse Stephanie et de l'Archiduc Rudolf!" Has so old a grower as Mons. Levet no more idea of the sense of propriety and the fitness of things than to give a Rose such a name? How very much wiser was my good old friend the late Mons. Souchet in naming his Gladioli! Pygmalion, Hecla, Le Vesuve, Norma, and such-like names are surely more fitting than these Madames, and Comtes, and Princesses with their long high-sounding names, some of which will be found in the following list.

I will take first as of the most general interest the class of Hybrid Perpetuals, of which we have the following already advertised—

Guillaume Guillemot (Schwartz).—Carmined Rose, with pale reflex; large, full, and globular. Growth vigorous. A seedling from Madame Charles Wood.

Empereur de Brésil (Souper et Notting).—Red shaded with blackish violet; very full. Growth very vigorous.

Comtesse Nathalie de Kleist.—Coppered red; reverse of the petals carmined. A new colour. Large, full, and cupped.

Madame Alfred Leveau (Vigeneron).—Bright carmined rose; large, full, fine form. Growth vigorous.

Mons. Thouvenel (Vigeneron).—Velvety red; large, full. Growth very vigorous.

Rosieriste Jacobs (Madame Ducher).—Fine velvety red shaded with black; large, full, well-formed, globular. Growth vigorous.

François Levet (Levet).—Chinese Rose, of medium size. Growth vigorous.

Comtesse de Camondo (Levêque et fils).—Fine bright rose shaded with violet; large, full, imbricated form. Growth vigorous.

Comte Frederic de Thun Hohenstein (Levêque et fils).—Deep crimson shaded with carmine; large, full, fine form. Growth very vigorous.

Auguste Buchner (Levêque et fils).—Bright scarlet shaded; large, full, imbricated form. Growth vigorous. Extra.

Madame Montet (Liabaud).—Very soft rose; large, almost full. Growth very vigorous. Very fine.

Anicet Bourgeois (Moreau Robert).—Bright cherry red; large, full, cupped, blooming in clusters. Growth very vigorous.

Georges Moreau (Moreau et Robert).—Very bright shaded red; very large, opening well, globular. Growth very vigorous.

Dumnaeus (Moreau et Robert).—Shaded red; very large, full, cupped, blooming in clusters. Growth very vigorous.

Souvenir de Madame Dioche (Pernet).—Carmine rose; large, almost full and globular. Growth vigorous.

TEA.

Antoine Devert (Gonod).—White, with sulphur yellow in the centre; reverse of the petals salmon rose; large, full, fine form. Growth very vigorous.

Baron Alexander de Vrints.—Pink, striped with red and white. New colour, of medium size. Growth vigorous.

Fiançailles de la Princesse Stephenie et de l'Archduc Rudolf (Levet).—Salmon orange yellow, of medium size. Growth very vigorous. A seedling from Gloire de Dijon.

Madame Caro (Levet).—Salmon yellow; of medium size, fine form, very full. Growth very vigorous.

Madame Chedane Guinnosseau (Levêque et fils).—Sulphured canary yellow; beautiful in bud; in the shape of Madame Falcot; large, full, fine form. Growth vigorous. A grand addition for market Roses.

Madame Amadin (Pernet).—Very bright rose, with white in the centre; very large, almost full. Growth vigorous.

Madame Joseph Schwartz (Schwartz).—White, tinged with flesh rose; full, of medium size. Growth vigorous. A seedling from Comtesse Labouthe. Extra.

Reine Maria Pia (Schwartz).—Deep rose, crimson in the centre; large, full. Growth very vigorous. A seedling from Gloire de Dijon.

Prince Prosper d'Arenberg (Soupert et Notting).—Salmon red, carmine in the centre, reverse of the petals clear carmine; of medium size, full. Growth very vigorous.

MISCELLANEOUS.

Madame Isaac Percire (Margottin fils).—Hybrid Bourbon. Beautiful vivid carmine; large, full, of immense size; perfect imbricated form, blooming all the season. Growth very vigorous. First-class variety.

Madame Cecile Bonner (Ducher).—Hybrid Polyantha. Bright rose, yellowish in the centre; flowering in clusters; very sweet, of dwarf habit. Very vigorous. This variety is a seedling from the Rosa polyantha, and will be very useful for bedding.

Blanche Moreau (Moreau Robert).—White Perpetual Moss. Fine pure white; large, full, opening well, of perfect form, blooming in clusters. Growth very vigorous.

Madame Julie Weidman (Soupert et Notting).—Salmon silvery rose, carmine and yellow in the centre; reverse of the petals violet. Large and full. Extra.

Such is the first instalment. We can hardly expect it to be the only one; but such as it is, we may say of the Roses armed with the descriptions, There are some novel things to be seen.—D., Deal.

GROWING GRAPES WITHOUT FIRE HEAT.

MR. F. WALKER'S article on page 477, no doubt written in good faith, is, I think, likely to be misleading to many, not perhaps so much to the professional man as the amateur. I have carefully read the article, and I cannot see the advantage of growing Grapes as described. I do not say they cannot be so grown, but a certain amount of artificial heat produces surprising results. I do not know in what part of the country your correspondent is situated, but I think he might have favoured us with that information. Grapes and good fruits are grown under glass without fire heat, but of course unless the weather is very favourable there is but little chance of keeping them, more especially if the house is used for other plants. In a cold house I should prefer the spur to the rod system, on account of ripening the wood. No doubt some will read with a shrug of their shoulders about your correspondent's Black Hamburg Grapes turning sour: this is, I presume, what we should call shanking. In my experience, after the Grapes are ripe, nothing will turn them sour. My chief objection to an unheated structure for Vines is that there are so many such buildings, and these ever increasing, that it causes a bulk of Grapes to be in the market, and spoils the sale of better fruit. Then, again, if the house is heated it is useful all the winter, and I believe the little

fire required to keep frost out is of the greatest benefit in ripening the wood, provided the house is well ventilated.

Reverting to the article in question, I am quite convinced that whatever advantage Mr. F. Walker may see in his practice would be outweighed were he to experiment with a little fire heat. The number of bunches given is satisfactory, but weight is always preferable. One of the best of Grapes after the Black Hamburg for cold houses is Black Alicante, but to keep it without fire heat is another question. This summer I had on newly planted Vines bunches weighing 2½ lbs., but I made no attempt to keep them. I only had one or two bunches on each, so they were not worth the trouble. Lady Downe's is the worst I know for cold houses; in the first place it is difficult to set, and then when the damp autumn days arrive the Grapes soon become unfit for use. In the southern counties this culture is carried on with greater success than I should ever expect to attain in this county if I felt disposed to try it. In advising those who are contemplating building a small house for Vine-growing, I always recommend them to have it heated. I know this principle is sound, and I have no doubt three out of four of your readers will agree with me. Do not let your readers suppose it is impossible to grow Grapes with success in cold houses, as I have done it myself, and after growing them so with the aid of a paraffin stove have kept them till Christmas; but the Black Hamburg does not improve by keeping, fruit of this variety losing colour fast after it is ripe.—STEPHEN CASTLE, *The Vineyard, West Lynn, Norfolk.*

[The Grapes referred to were grown in the Isle of Wight. The advice to have vineries heated is sound.—EDS.]

CHAPTERS ON INSECTS FOR GARDENERS.—No. 15. NEW SERIES.

"BEETLE-CRUSHERS" is the uncomplimentary phrase by which sundry newspapers are fond of designating the feet of the damsels in some of the American States, where fresh air and exercise favour a pedal development that is useful if not elegant. Probably there is a natural tendency, more marked in woman than in man, leading us to step upon a beetle purposely that may happen to be in our path; and it is one of the traveller's tales, often told though not always believed, that in warmer countries than our own the beetles appear at times in such numbers that it is impossible to avoid crushing them along the roads. It is even asserted that the insects have so swarmed occasionally as to obstruct the passage of vehicles by clogging the wheels! The beetles that are in popular language called "chafers"—for so the name is properly spelt, not with the double f, the root being an old Saxon word meaning to devour—are, I believe, of all the beetles occurring in Britain most notable for appearing in swarms, partly because they are frequently bred numerous in a small space, but partly also because they have a liking for each other's society. These chafers form the concluding group of the Lamellicorn beetles, with leaf-like horns, and so resembling the dung-beetles last described. In habit, however, they are generally vegetarian, and amongst the insects that are unfriendly to horticulture. We, however, suffer but slightly from these as compared with other lands: on the continent, for instance, the harm done by the larva of the cockchafer in some seasons is fearful. The perfect insect or beetle is also at times so numerous as to strip off the leaves from entire plantations, leaving an appearance that almost suggests to the observer that there had been a colony of locusts upon the spot. As producers of insect music the chafers are quite able to rival the dros. The use of this humming or buzzing is perhaps chiefly protective.

It is not needful to describe an insect so well known as is the common cockchafer (*Melolontha vulgaris*), which generally shows itself in beetle form during the month of May; nor is the larva unknown to most gardeners, though its life history may not have been worked out by them, since they are naturally anxious to destroy all examples that may turn up of the "white grub," as it has sometimes been called. In Ireland, observes one entomologist, folks often call it the "Connaught grub;" why he does not profess to say—a fleshy rather mis-shapen creature, and should it be near its full size, one apparently helpless when unearthed, from the fact that the abdomen is gorged with food. Under ground, indeed, this grub does not move about much, the legs being feeble; but there is plenty of power in the head and jaws. Owing to the long duration of their larval state (nearly three years) cockchafers, while working unseen though not unnoticeable, do great harm to pasture and corn fields, and also in some gardens. Fortunately they have several enemies amongst the birds, the rook being an eager follower of the plough or spade to pick up larvæ that are dislodged. Besides birds some quadrupeds and reptiles feed upon them as larvæ or beetles, and they have insect foes, yet somehow their numbers keep up from year to year.

Several writers have asserted that cockchafers are particularly abundant triennially, but I have not found this confirmed by observation. Amongst the many applications recommended as remedies for the grub few are more effective than a solution of ammonia in some form, or else "gas lime," when these can be brought to operate upon the spots where the grubs are congregated. A smaller and comparatively harmless beetle that is occasionally supposed to be a young cockchafer is the pretty *Amphimalla solstitialis*, which emerges later in the season. From these species we gladly proceed to notice a more pleasing insect, the Rosechafer (*Cetonia aurata*), and none can deny that the green and gold surfaces, marked on the upper side with curiously curved lines and dots of white, are handsome as seen when the beetle is at rest, or should it be flying it displays to us as well a delicately veined pair of gauzy wings. I wish, however, that I could believe the species is as harmless as some people think it; but it certainly visits the Rose for the purpose of biting the petals, and it is stated on good authority to do damage now and then to the flowers of the Strawberry, and Candytuft proves an attraction. The bloom of the Elder and Privet bring to them *C. aurata*; and I recollect noticing one June morning a profusion of these beetles in the lanes intersecting some Fulham market gardens, where they caused some astonishment. The circumstance, however, was rather a puzzle, for it seemed most probable that the insects must have lived in their larval condition somewhere not far off, and there were not many trees in the immediate neighbourhood, though the usual food of the larva is presumed to be decaying wood. Kirby and others have discovered a larva they regarded as *C. aurata* in the nests of ants; and although on investigation

Fig. 88.

Fig. 89.

Fig. 90.

amongst gardens I failed to find any subterranean beetle grub was known which corresponded with the larva of the species, I suspect it is also a root-eater. Mr. F. Smith relates that a friend one day passing the stump of a tree gave it a kick, and to his surprise it fell to pieces, while there tumbled out of it above a hundred of these pupæ enclosed in their close cocoons of gnawed wood. A rarer beetle than the Rosechafer, and one which is only designated by the Latin name of *Gnorimus nobilis*, resembles the foregoing, but is rather less. The larva has been taken near London in the solid wood of the Apple. The garden species that is oddly named the Bracken-clock, or in some districts by the still stranger name of "Cockerbundy," presumed to be from the Welsh, *Coch-y-bondhu*. In length it averages half an inch, the head and thorax being dark green, and the elytra or wing cases rusty brown. These do not quite reach to the extremity. This insect, probably *Phyllopertha horticola*, is far too partial to gardens, and pursues a similar course to the cockchafer. The eggs are laid upon the ground, and the newly hatched grubs burrow in and feast on the roots of any plants that may be conveniently near, during June and July pay attentions to flowers in gardens or in orchards, and they have been caught in the act of nibbling fruit newly set. At night they may be swept off plants and shrubs into a net. Of late, however, this pest seems to become less abundant.

Our next group of beetles, which completes the first great division of the Pentamera, is called *Priocerata*. These, that is to say in plain English, are the "saw-horns." The moderately long antennæ are toothed or serrated, with some exceptions. This splits into two very natural families, one being hard-bodied the other soft-bodied, with antennæ and legs rather longer. The Elaters, a "name of terror," stand out prominently in the first family—beetles that are harmless enough in their beetle aspect, and which do really nothing to provoke us to destroy them, except that they will prove themselves the parents of another generation of wireworms; for though this appellation has been, and still is, conferred upon various insects, of right it belongs to the larvæ of the Elaters, or "skip-jacks" or "click-beetles," and especially to

that of *E. lineatus*. Though this is a prominent garden foe, others beside it occur on cultivated land; but others, like *E. sanguineus*, a blackish-red beetle found in woods, feed chiefly on the roots of wild plants. The wireworm (fig. 90) is dreaded not only as a consumer but as a waster, for as it works sinuous tracks amongst the roots it does a greater mischief than do larger grubs which keep near to one spot. So tough and flexible is the skin of one of these that a heavy roller passes over it without doing it injury, and the many expedients tried for their destruction have only a partial success. The beetles are far less vigorous than the larvæ, and they are provided with a singular means of defence or escape, which has conferred upon them their popular name. By means of the movement of a joint with which the breastplate is furnished in and out of a groove, the Elaters can spring into the air when lying upon their backs. This organ is shown at rest in fig. 88, and sideways as in use in fig. 89. In this same family we have a few English representatives, small in size, of the gorgeous *Buprestidæ* of warm regions.—J. R. S. C.

SAWDUST FOR PROPAGATING PLANTS.

YOUR correspondent "W. K.," page 458, strongly recommends cocoa-nut fibre refuse for propagating, and he is perfectly right. I may state that I have never found any material that produces roots so quickly, surely, and numerous, in all plants that I have tried in it as sawdust fresh from the forester's sawmills, and it does its work perfectly for twelve months without being renewed. Pitcher-plants, including such varieties as *lanata* and *sanguinea*, strike freely in sawdust, and scarcely a cutting of any plant fails in it. I never saw plants make such enormous numbers of rootlets in any other material. I once potted a Pine Apple in it, and in a very short time the whole dust was so permeated with roots that when they were washed clean they resembled a wig of roots more than anything else. A Camellia was tried in it with the same result.

These facts may be of service to many who are able easily to obtain sawdust who cannot so easily procure silver sand or cocoa-nut fibre refuse. The sawdust used here is from Spruce, Larch, and Oak, all mixed together and laid about 4 inches thick over a heated chamber.—D. THOMSON, *Drumlanrig*.

CHRYSANTHEMUM AND FRUIT SHOWS.

LIVERPOOL.

ST. GEORGE'S HALL in this city is a noble building with imposing architectural adornments, and it was fittingly occupied on the 23rd and 24th ult. by some of the finest collections of plants, cut blooms, and fruit that have been seen at any of the autumn shows of the year. The weak section of the Show was that which included the specimen large-flowering Chrysanthemums, which were too closely and formally tied, the twisted stems being very apparent—not one bent stem should be seen in a well-trained plant; still the winning groups contained good examples of culture. The strong sections were those devoted to cut blooms and fruit; the former, especially those in the winning stands, being of remarkable excellence; the latter, notably the Grapes and Pines, indubitably the best that have come under our notice during the month. The specimen Pompons were also remarkable for their high artistic finish and the quality of the flowers and foliage. The blooms were disposed with mathematical precision in concentric circles, only one flower being retained on each shoot. Some of the plants were too flat, yet they were extraordinary examples of skilful manipulation, though necessarily stiff and formal; such plants are never seen at southern shows. Following the classes in the order of the schedule we commence with a notice of the

SPECIMEN PLANTS.—In the class for six large-flowering Chrysanthemums Mr. J. Stephenson, gardener to Major Pilkington, gained the first prize with fresh and well bloomed plants of Lady Slade, Jardin des Plantes, Mrs. Geo. Rundle, Prince Alfred, Barbara, and Nil Desperandum. Mr. W. Tugwood, gardener to J. G. Morris, Esq., Allerton, was second with good examples of Jardin des Plantes, Mrs. Geo. Rundle, G. Glenney, and Fingal. Mr. J. Hughes, gardener to R. G. Morran, Esq., a rather close third. In the class for four plants Mr. W. Tugwood was deservedly awarded the first prize for good examples of Lady Talfourd, Empress of India, Prince Alfred, and Mrs. G. Rundle; Mr. Stephenson was second, and Mr. J. Hughes third.

In the class for six Pompons Mr. Tugwood was first with excellently grown and symmetrical specimens of St. Michael, Lilac, White, and Golden Cedo Nulli, and Prince Alfred. Mr. S. Whitfield, gardener to J. T. Cross, Esq., Aigburth, was second with little smaller but equally fresh plants. In the class for four plants Mr. Tugwood was again first, Mr. S. Whitfield second, and Mr. C. Finnigan third, all showing well similar plants to those above mentioned, except *Aurore Boreale*, which was staged in the first-prize lot. An extra prize in this class was awarded to Mr. Blackmore, gardener to Captain Pemberton, for very neat specimens. Mr. Woolwright, Mossley Hill, was first in

the class for two standards with good plants of George Glenny and Mrs. G. Rundle; Mr. Foster, gardener to J. Brancker, Esq., second; and Mr. J. Hughes third. For two pyramids, Mr. J. Stephenson and Mr. J. Hughes were the prizetakers in the order named. Mr. Tunnington, Calderstone, staged six good standards in three varieties not for competition.

CUT BLOOMS.—The competition in nearly all the classes was good, many of the incurved flowers being excellent in form, substance, and colour. In the class for twenty-four blooms, incurved, there were four exhibitors. The stands shown by Mr. F. Faulkner, gardener to F. R. Leyland, Esq., Woolton Hall, and Mr. Wm. Mease, gardener to C. W. Newmann, Esq., Wyncote, were very close, and the individual flowers required careful examination from the Judges before deciding. The premier position was secured by the first-named exhibitor, who won by two points; very fine were the blooms of Golden Empress, Mr. Howe, Princess of Wales, Venus, Queen of England, Alfred Salter, White Globe, Barbara, and White Venns. Mr. Mease's fine stand of flowers contained the finest bloom in the Show of Inner Temple, also excellent examples of Mrs. Heale, Miss Mary Morgan, Princess of Wales, Beauty, Nil Desperandum, Queen of England, Hero of Stoke Newington, and Mrs. Halliburton. Mr. H. Elliott, gardener to W. G. Bateson, Esq., New Heys, Allerton, and Mr. Wm. Todd, gardener to J. W. Cropper, Esq., Aigburth, were placed equal thirds. Mr. Elliott's blooms were very fresh and good in colour, but rather undersized; the blooms in Mr. Todd's collection being large but rather flat. In the class for eighteen blooms, incurved, Mr. F. Roberts, gardener to W. D. Holt, Esq., West Derby, gained the first prize with very fine solid blooms, the best being Cherub, Sir Stafford Carey, White Beverley, Golden Beverley, Queen of England, and Baron Beust; Mr. J. Peers, gardener to R. Rayner, Esq., being a good second; and Mr. J. Foster third. In the class for twelve blooms Messrs. Faulkner, Mease, and Green were the prizetakers in the order named. Mr. Jellico, gardener to F. H. Gossage, Esq., Woolton, was first for six blooms with an even stand; Mr. E. Green was second, and Mr. F. Roberts third. Japanese varieties were not shown in such large numbers as the incurved nor in such excellent condition, yet the winning stands of Messrs. Faulkner and Mease were most creditable considering the short time Liverpool growers have taken to growing these peculiar and most interesting forms of the Chrysanthemum. The two stands in question were the chief feature of attraction in the Show. Mr. Faulkner, who secured the first position by one point, staged good blooms of Elaine, Peter the Great, Fair Maid of Guernsey, Apollo, Orphée, Ethel, M. Lemoine, and Gloire de Toulouse; Mr. Mease having equally good examples of Meg Merrilees, Chang, Bismarck, Red Dragon, La Nympe, James Salter, and Père Delanx. In the class for twelve blooms Mr. Todd was first, and Mr. J. Jellico second. For Anemone-flowered Chrysanthemums Mr. Faulkner was the only exhibitor, and was awarded a first prize. The Horticultural Association will do well to offer some greater inducement to growers of this type of Chrysanthemums.

STOVE AND GREENHOUSE PLANTS.—The winterly weather prevented many exhibitors bringing their plants, and Mr. W. Peers, Wavertree, was the only exhibitor of twelve specimens, and was awarded a third prize. Mr. Faulkner was the principal exhibitor of stove or greenhouse Ferns, and obtained the first prize for excellent plants of *Adiantum Flemingii*, *Davallia Tyermani*, *Nephrolepis davallioides*, and others. Mr. J. Peers was an easy first with admirably grown Palms or Cycads; Mr. Faulkner being second. Mr. J. Peers was again first for one Palm, showing a magnificent *Cocos Weddelliana*; Mr. S. Whitfield second; and Mr. W. Peers third. In the class for three Orchids Mr. Sherwin, gardener to W. Sparke, Esq., Huyton, was first with a very fresh *Vanda cærulea*, *Cypripedium insigne* with forty blooms, and a good pan of *Sophranitis grandiflora*. Mr. Faulkner was a very good second, and J. Foster third. Mr. Blomily, Oaklands, Aigburth; Mr. W. Pratt, gardener to Lord Hill, Hawkestone; and Mr. J. Peers were the prizetakers for *Calanthes*. For three Epiphyllums Mr. Barber, gardener to Mrs. Barnsley, Aigburth, first; Mr. W. Bustard, gardener to J. Lewis, Esq., second; and Mr. Gore, gardener to J. Holder, Esq., third. Messrs. J. Peers, Hutton, Green, Hughes, and Hurst were the principal prizetakers for *Primulas* and *Mignonette*. Table plants were very good, but some of them too large. The prizetakers were Mr. W. Peers; Mr. Wylie, gardener to A. Holt, Esq., Aigburth; Mr. Sherwin, and Mr. Pratt. Roman Hyacinths were numerous and excellently shown, the prizes being obtained by Messrs. Faulkner, J. Peers, and J. Kelly, gardener to R. Singlehurst, Esq., Aigburth.

BOUQUETS were numerous, and many of them good; Mr. Evans, gardener to Mrs. Lockett, obtaining the first prize; Mr. Blomily and Mr. Wylie being second and third respectively. In the nurserymen's class Messrs. Jones & Sons, Shrewsbury; Messrs. Turner Bros., Liverpool; and Mr. C. Rylance, Ormskirk, were awarded the prizes in the order named.

FRUIT was largely shown and in excellent condition. In the class for twelve dishes, Pines excluded, Mr. Hannagan, gardener to R. C. Naylor, Esq., Hooton Hall, was first, having fine examples of Muscat of Alexandria, Gros Colman finely coloured and large berries, Alicante, and Lady Downe's Grapes; Conqueror of Europe Melon, very fine; Strawberry Apple; very large Beurré Diel, Beurré Clairgeau, and Glou Morceau Pears. Mr. Mease was second with good Gros Guillaume, Mrs. Pince, White Tokay, and Alicante Grapes, Coe's Golden Drop Plums, Beurré d'Amanlis Pears, and a dish of Straw-

berries. Mr. Hannagan was again first for six dishes, staging good Grapes and a William Tillery Melon. Mr. J. Wallis, gardener to Rev. W. Sneyde, Keele Hall, Stafford, was an excellent second, his notable dishes being a good bunch of Golden Queen Grape and Ribston Pippin Apples; Mr. Stevenson, gardener to R. Horsfall, Esq., being third with a very good collection. In the class for two Pine Apples Mr. McGaw was first with two remarkably fine Queens, Mr. Faulkner and Mr. Tunnington being second and third also with good fruits. Mr. Tunnington took the first prize for one Pine, no name being attached to the cards of the second and third-prize fruits. There were ten entries for two bunches of black Grapes, Mr. Wallis taking the lead with excellent and well-finished bunches of Gros Guillaume; Mr. Stephenson being second with good Aliantes; and Mr. C. Finnigan, Huyton, third; Mr. R. Elphinston, gardener to J. Heywood, Esq., Derbyshire, being awarded an extra prize. For two bunches of Muscat of Alexandria Mr. Hannagan; Mr. J. Hurst, gardener to W. B. Bowering, Esq.; and Mr. F. Roberts were the successful prizewinners. For four bunches of Grapes, distinct, Mr. Wallis gained the premier award, being closely followed by Mr. Hannagan, and Mr. Finnigan was a good third. For two bunches of white Grapes, not Muscat of Alexandria, Mr. J. Wallis was again first with Golden Queen, followed by Mr. Elphinston with Buckland Sweetwater, and Mr. Gore. Splendid examples of culture were staged in the above classes. Pears were largely shown; and in the class for eight varieties, distinct, Mr. Hannagan was first with good dishes of Marie Louise, Beurré Clairgeau, Duchesse d'Angoulême, and Joséphine de Malines; Mr. Dullachie, gardener to Mrs. Uzwilschenbart, second; and Mr. Kelly third. For four dishes Mr. Hannagan again took the lead, followed by Mr. Kelly and Mr. J. Lowndes, gardener to S. S. Parker, Esq. For single dishes of dessert and stewing Pears Messrs. Mease, Hannagan, Lowndes, Evans, and Whitfield were the prizetakers. For six dishes of dessert Apples Mr. Hannagan was first with Ribston Pippin, Blenheim Pippins, and Kerry Pippin; Mr. Lowndes second; and Mr. C. Rylance, Ormskirk, third. In the class for three dishes Messrs. Stephenson, Lowndes, and Evans took the prizes in the order named. Mr. Rylance was first for eight dishes of kitchen Apples, with fine fruit of Lord Suffield, King of Apples, and Surprise; Mr. Hannagan being second with Warner's King, Lord Suffield, and Reinette de Canada; and Mr. Kelly third. There were seven entries in this excellent class. For four dishes Mr. H. J. Johnstone was first, his best varieties being D. T. Fish, Warner's King, and Rylance's Surprise; Mr. Dullachie second; and Mr. Vaughan third. In the remaining classes Mr. Johnstone, Mr. Rylance, and Mr. T. Robinson, gardener to W. B. Halhead, Esq., were the chief prizetakers.

MISCELLANEOUS EXHIBITS.—Some excellent Alicante Grapes and two Mammoth Gourds, weighing respectively 93 lbs. and 97 lbs. were exhibited by Mr. John Smeatham, gardener to F. D. Nuttall, Esq., St. Helens, who was awarded a cultural commendation. Mr. Cannell of Swanley, Kent, exhibited a fine collection of cut blooms of single and double zonal Pelargoniums, many of the varieties being new, with pips of an immense size, and most brilliant in colour. Mr. Cowan of the Garston Vineyard exhibited a group of choice flowering and foliage plants, tastefully arranged and highly effective. Messrs. R. P. Ker & Sons and Turner Bros. also exhibited attractive groups of plants, the latter showing some beautiful wreaths and bouquets. The above groups added materially to the general effect of the Show, which was the first autumn Exhibition of the Horticultural Association, and was highly creditable to both the managers and competitors.

BIRMINGHAM.

Spacious as is the handsome Town Hall in which the Show was held on the 24th and 25th ult., it was altogether inadequate for an Exhibition of such magnitude as the one under notice. The principal Hall was crowded, or rather overcrowded, with grand specimens of large-flowering Chrysanthemums, and in the gallery the Pompons were packed in a broad dense mass. The appearance of this large bank of flowers was unquestionably improving, but it was utterly impossible for anyone to examine the plants individually, and the Judges must have found it extremely difficult to make their awards. To have properly displayed the plants, flowers, and fruit placed in competition a building twice the size would not have been too large. The specimen plants referred to were of extraordinary size, the display of cut blooms being correspondingly inferior; yet in this section there was a marked improvement since last year, and a few excellent examples were noticeable in some of the stands. *Primulas* were grand; some good stove and greenhouse plants were staged, and fruit was well represented. The effect would have been better had the "table plants" been arranged down the central tables, but when managers of shows are overwhelmed with exhibits they have to do what they can rather than what they wish, and much credit is due to the Birmingham officials for disposing of the various collections so well as they did. The system of judging and placing the cards was in all respects satisfactory, and altogether the Show was of great excellence. We can only refer briefly to the classes.

SPECIMEN PLANTS.—In Class 1, for nine large-flowering Chrysanthemums, five collections were staged, the first prize being £3, and in addition a silver cup value £5, given to the winner as the "premier" prize. Mr. Stacey, gardener to F. Osler, Esq., Edgbaston, clearly proved himself the premier exhibitor, not only by winning the cup, but by his success in other important classes. His nine cup plants

were marvellous examples of culture. They were about 2 feet high from the pots, with slightly convex surfaces from 5 to 6 feet in diameter. Nor were the plants "staked out" so as to make them appear as large as possible; on the contrary, the flowers appeared rather to have been drawn together as if to reduce the size of the specimens to permit them to be passed through the doors of the building. This somewhat marred their appearance, as it exposed the bent stems. Had these specimens been tied out as thinly as some that have been exhibited this year, notably at Kingston and Westminster, they would have been 9 feet in diameter. The smallest, and probably the most meritorious, specimen was *Bronze Jardin des Plantes*, with nearly or quite a hundred flowers of superior quality. Such a large and well-finished example of this variety has probably never been seen before. The specimens of the *Mrs. Rundle* type were crowded with excellent flowers, from two hundred to three hundred on each plant; indeed every plant was of wonderful excellence, and showed how much could be accomplished by attention and good culture. Mr. J. Crook, gardener to W. Milward, Esq., was a close second. The training was less cramped, more natural, and the foliage and blooms were excellent, but the stems of the back plants were a trifle weak. It was hard to lose with a collection that would probably have secured the foremost position at any other show that has been held this year. Mr. F. Denning, gardener to J. Jaffray, Esq., was placed third with smaller, yet good, and the most correctly trained plants of all. An extra prize was worthily awarded to Mr. Dyer, gardener to T. W. Webley, Esq., in this great and admirably contested class. In the class for six plants Messrs. Stacey and Dyer were the respective winners; for three plants Mr. Crook, and Mr. Jinks, gardener to J. E. Wilson, Esq., all the specimens being fine, those of the last-named exhibitor rather small but admirably trained. After such splendid examples of culture as those referred to the single specimen class was disappointing, the plants being overtrained and lacking vigour, and the class might well have been dispensed with.

Pompons were numerous, very large, and as none of them had been disbudded, densely flowered. In the class for six plants Mr. Stacey was again to the fore with free informal specimens, closely followed by Mr. Newell, gardener to J. Hayman, Esq. For three plants the redoubtable Mr. Stacey was once more the victor, Mr. Jinks second; and for a single specimen Mr. Dyer was the winner with the freshest and most naturally trained plant in the Show, not a stake nor bent stem being visible. Mr. Newell was an excellent second in this class, and Mr. Stacey was awarded an extra prize. All the plants in these classes were very fine, but some of them too flat and closely trained. In the class for one Japanese *Chrysanthemum* Mr. Denning won with a large and attractive example of *Elaine*, Mr. Jinks following with a smaller specimen of the same variety. It is highly probable if some of the *Chrysanthemum* Societies were to offer prizes for specimens of Japanese varieties that something striking would be produced in a year or two, and the experiment might well be tried. It is worthy of note that the best plant in the Show at Kingston was the Japanese variety *La Nympe*, and the remarkable standards exhibited at the Aquarium in 1879 proved that some of the Japanese forms are well adapted for specimens.

CUT BLOOMS.—This, the strong feature at some shows, was the weak one at Birmingham. The local growers do not appear to devote their energies to the production of superior flowers for cutting, and it must be added they have little inducement to do so, the prizes being small. In the class for eighteen blooms Mr. Shingler, gardener to T. Tonks, Esq., Harborne, was placed first; Mr. Palmer, gardener to R. C. Bradley, Esq., Handsworth, second; and Mr. Comfort, gardener to G. A. Everitt, Esq., Knowle Hall, third. Mr. Palmer's blooms were the best in form, but the stand was deficient in highly coloured flowers. Mr. Shingler's flowers were flatter, but fresher and brighter, and hence, we presume, the verdict of the Judges. Messrs. Comfort, Shingler, and Palmer were the respective winners with stands of twelve blooms, and for the same number grown within three miles of the Exhibition the prizes went to the two last-named exhibitors, and Mr. Yallier, gardener to J. Marigold, Esq. Most of the stands were irregular, the best blooms being Mr. Palmer's *Golden Empress* of India, and Mr. Comfort's *Hereward*, which were splendid. Small special prizes were offered for Japanese blooms, but we only saw one inferior stand. Superior stands of these varieties should be seen at all shows, as they always attract the attention of visitors.

PRIMULAS.—Cultivators who have not seen *Primulas* as they were exhibited at this Show have no idea of the excellence to which the plants can be grown. Nine classes were devoted to them, and the display was magnificent. For Mr. Thomson's special prizes for twelve plants Mr. Ashman, gardener to Mrs. W. G. Madeley, Yardley, was first with wonderful examples, the foliage having a spread of 2 feet, the plants having from five to seven vigorous trusses, each about 15 inches high from the surface of the pots; the varieties, Thomson's strain, being excellent. Mr. Caldicott, gardener to W. Matthews, Esq., Edgbaston, was a very close second with dwarf, sturdy, and splendidly flowered examples; and Mr. Denning third with fresh and fine plants of great excellence. This exhibitor secured Mr. Tomkins' prize, followed by Mr. Jinks, both exhibiting well. The Society's prizes for twelve and six plants (nurserymen) were won by Mr. Tomkins, a celebrated grower, who was first in both classes, and Messrs. Pope and Sons. Mr. Tomkins' plants combined freshness with vigour, and large flowers, the darks rich and the whites pure. In all good qualities this collection was remarkable; it has probably never been

surpassed and seldom equalled. Messrs. Pope's were also good. The prizes offered for gardeners in the classes devoted to them were won by Messrs. Jones, gardener to S. Eaton, Esq., Harborne, Ashman and Jinks, firsts, followed by Messrs. Caldicott, Jinks, Leested, and Chadwick, all of whom staged collections in which superior culture was unmistakeably apparent, and all who contributed to these classes deserve high commendation.

STOVE AND GREENHOUSE PLANTS.—Mr. Dyer won the chief prize for nine specimen plants, all of which were good, the most noteworthy being *Eucharis amazonica* with thirty spikes, each averaging five flowers. Mr. Herne, gardener to T. Hall, Esq., Warley Hall, was second, his collection including telling specimens of *Plumbago coccinea*, not often seen so good, and *Eupatorium odoratum*. Mr. Crisp, gardener to B. Scarf, Esq., secured third honours. For six plants Messrs. Jinks and McGregor were awarded the prizes for excellent exhibits. *Poinsettias* were highly meritorious. For three pots, not less than five heads to each, Mr. Herne was first, each pot (a 12-inch) containing twelve plants a foot to 18 inches in height with good foliage and heads. These pots, as may be imagined, produced a brilliant effect. Messrs. Crook and Dyer followed with excellent exhibits. Mr. B. S. Williams' prizes for table plants in pots not exceeding 6 inches in diameter brought out some excellent collections, and the prizes were awarded to Messrs. Herne, Jinks, and Palmer in the order named. The first-prize plants were perhaps the best in quality, but too large, except for a Guildhall banquet, and as gentlemen's gardeners are not often expected to furnish tables of that character the chief prize, we think, ought to have gone to Mr. Jinks, whose plants were of the right size for a gentleman's table and were of good quality. Broad-leaved *Dracenas* in 6-inch pots are too obstructive for this purpose, and the first-prize collection contained four of them. We direct attention to this class, not as questioning the ability of the Judges, who were competent men and discharged their duties carefully and well, but to point out the desirability of limiting table plants to 5-inch pots, as if plants cannot be grown in them suitable for the purpose indicated they are not worthy of a prize; while if really well grown in 6-inch pots they must inevitably be too large, as in this instance, except for public banquets. We have seen so much divergence of opinion amongst judges in adjudicating on table plants, so much perplexity and hesitation, so many awards made with reluctance to plants of good quality but too large, that we consider the suggestion we have made of practical importance, and it is commended to the attention of the committees of horticultural shows generally. Prizes were offered for various other plants, but the exhibits were not generally noteworthy.

FRUIT.—Although the display was not quite equal to that of last year some very good collections were staged. Mr. Crawford, gardener to J. Cartland, Esq., King's Heath, secured the premier award for six dishes with Grapes, a Pine Apple, Pears, and Plums, all of good table quality. Mr. Willis, gardener to W. Foster, Esq., Tenbury, was second, and Mr. Jinks third. For four dishes Mr. Stacey was the chief winner. He staged good Grapes and splendid *Pitmaston* Duchess Pears. Messrs. Jinks and Denning followed in the order named. Mr. Comfort secured the first prize for three dishes of black Grapes with fine and well-coloured examples of *Alicante*; Mr. Dyer being second with larger bunches and smaller berries, and Mr. Rawbone a good third. An extra prize was deservedly awarded to Mr. Crawford. White Grapes were less meritorious, except the first-prize *Alicantes* of Mr. Stacey, which were in excellent condition; and good examples of *Trebbiano* from Mr. Crawford. Mr. Comfort easily secured first honours for a single bunch of black Grapes with a large, handsome, and well-formed bunch of *Gros Guillaume*—quite the premier bunch of the Show. Mr. Stacey had the corresponding prize for white Grapes with small but good *Muscats*. Mr. Griffiths, gardener to E. Tonks, Esq., staged a large and superior *Queen Pine* and secured the chief prize, followed by Mr. Freeman, gardener to Z. Walker, Esq., Hall Green, with *Black Jamaica*. For twelve dishes of Apples Messrs. Jinks and Willis secured the prizes; they were also second and third for six dishes, Mr. Griffiths being first. The specimens were not large, but many of them were richly coloured. Mr. Willis secured the first prizes for twelve and six dishes of Pears with very good fruit. Prizes were offered for single dishes of fruit, but only the very fine *Duchesse d'Angoulême* Pears from Mr. Comfort were of special excellence, and these had probably been grown under glass.

BOUQUETS.—The majority of these were too crowded. In the nurserymen's class Mr. Hans Niemand (Mr. Spinks, manager), was worthily placed first with a tasteful arrangement of *Eucharises*, red *Bouvardias*, *Camellias*, and *Gauze Fern*, Messrs. Pope & Sons following rather closely. In the gentlemen's gardeners' class Messrs. Jinks, Jones, and Crisp were the prizewinners, Mr. Merriman, gardener to H. A. Hayman, Esq., receiving an extra prize. Although some exception was taken by a few critical onlookers to the awards, they were undoubtedly correct.

MISCELLANEOUS EXHIBITS.—Mr. Vertegans of the Chad Vale Nurseries exhibited some splendid large flat baskets of flowers; one filled with semi-double blush *Primulas*, raised from seed, was very beautiful, as also was another furnished with *Poinsettias* and *Tuberoses*; he had also fine baskets of *Roman Hyacinths*, *Bouvardias*, *Zonal Pelargoniums*, *Azaleas*, and mixed *Primulas*. Mr. Hans Niemand exhibited some rustic vases, durable and artistic, made and tastefully furnished by Mr. Spinks; one of them, containing a *Dracæna*, with *Cyclamens*, fine trusses of *Luculia gratissima*, and

Isoplepis, was very beautiful. These vases are suitable alike for rooms and conservatories, and the water can be drained from them without touching the floor or carpet. Mr. Cannell had a brilliant stand of Zonal Pelargoniums in superior varieties, and some very rich *Primula* blooms. Mr. Taylor, gardener to J. Evans, Esq., Hammerwich, Lichfield, exhibited an extraordinary *Cineraria* to show the efficacy of his "new plant manure." This plant was stated to have been raised from seed sown on April 30th; it was 2½ feet high and the same in diameter, with vigorous branching growths, thick dark green foliage, and large flowers. Mr. Latham, Mr. Redfern, and other officials rendered the Show as pleasant as it was successful.

OXFORD.

This Society held its annual Show on the 23rd and 24th ult., in the spacious Corn Exchange, Oxford. The exhibits were numerous. Most of the plants bore good blooms, although, as elsewhere this season, many incurred varieties, especially of the Rundle type, were not first-rate. One specimen of George Glenney had about forty-five blooms. Cut blooms were not largely shown, but some excellent stands were staged. A special feature in this Show were the grafted trained standards of four or more varieties in one plant, some of them exceedingly handsome. The Oxfordshire Society is almost entirely composed of amateurs, and has about 250 members, from the shoemaker to the Oxford professor. The Society enjoys good patronage, and gives very substantial prizes. The Duchess of Marlborough visited the Show during the day, and the Exchange was very crowded all day, and altogether the Show was a great success and excellently managed by the Secretary, Mr. A. Greenaway. The Judges were Mr. C. Hill, Oxford, and Mr. N. Davis, Camberwell.

HOW I FAILED TO GROW GOOD ASPARAGUS.

ASPARAGUS is one of the most important vegetables grown in the kitchen garden, as it comes into season at a time when vegetables are very scarce; it is therefore rather serious for the gardener when the crop fails, yet I have failed to grow good Asparagus, and will point out what my system has been. The soil in the garden under my charge is a stiff shallow loam; the subsoil is a kind of shale, and rock beneath. Most vegetables, Strawberries, Peach, Nectarine, Apple, and Pear trees, all succeed well. The piece of ground where I intended to make the beds was rather wet, so in October I marked out four beds and two ridges. The soil was removed and 6 inches of clinkers placed at the bottom, which were covered with fern to keep the drainage clear of soil. Afterwards all the soil was returned and some well-decomposed dung was placed upon the bed. Trenching was then commenced by taking out 1 yard width of soil and wheeling it to the other end of the bed to fill up the last trench. I placed in 3 inches depth of well-decomposed dung and a sprinkling of inch bones, when the first spit of soil and shovellings were placed upon the dung. I then put a layer of dung, fresh loam, and bones well mixed together upon the first spit of soil until the trenching was finished. A covering of the same mixture as that over the drainage was placed on the surface. The beds were then dug one spit deep and thrown up into ridges a yard wide, which in March were forked down. Early in April they were again forked over and prepared for the plants. The beds were 4 feet wide with three rows of plants, in each 1 foot apart each way. The paths were 2 feet 6 inches wide.

The Asparagus was planted as soon as growth commenced; the line was placed the length of the bed in the centre, and with a hoe I drew the soil towards the edge of the bed. At the bottom of the trench a mixture of dung and loam was placed, and covered with sea sand. The roots were carefully spread out, a man following to cover the plants with loam and manure. When all the beds were planted a slight coating of sand was thrown over them, raking, levelling, and edging them in the usual way. Owing to the mild showery weather at the time, the plants soon started and grew remarkably well for the first two years. The beds were kept free from weeds, and a small Dutch hoe was frequently run over the beds to keep the surface open. In November when the haulm was quite ripe it was cut down, and the beds were carefully pricked over with a steel fork, a dressing of fresh dung being placed on them. In March the dung was raked off the beds and dug into the paths. After two years' growth the Asparagus was very fine and I expected a good supply in the spring, but time passed and no growths appeared. I then examined the plants to find that after all my trouble and care nearly half of them were dead. I felt quite disheartened, as the two ridges were in the same condition. I have planted at different times three or four sets of beds, but without drainage, employing the same compost as described above, but with more sand in the mixture, and the result has been a failure in each case. It is very remarkable that all the plants grew so satisfactorily for two years, and the third year nearly one-half died. I have tried seed sown in drills, the plants being thinned to 1 foot apart; also plants one, two, and three years old, with no success. I shall be glad to obtain any

information upon growing Asparagus in such soil as I have described. In sandy loam I have been successful with it, but a stiff retentive loam is very different.—JOHN NUNNS, *Wimbledon*.

GARDEN REFUSE AND ITS USES.

MR. RECORD'S remarks on this subject on page 476 were well worthy of a place in the *Journal of Horticulture*, as fortunately, or unfortunately as some may think, a rubbish heap or heaps are to be found connected with every garden. These are frequently much too conspicuously situated. In many instances there are two such heaps—one to which all rubbish from the pleasure grounds is taken, the other for that of the kitchen garden. Here we have three separate heaps, all of which in the course of twelve months become of considerable size, and eventually prove extremely useful for various purposes. For the rubbish which accumulates in the pleasure grounds a large trench, from which fully fifteen loads of earth was taken, was cut at the back of a conveniently situated shrubbery. Into this trench, commencing at one end, all the sweepings, parings of turf, old bedding plants, weeds, and any leaves not good enough for hotbeds are thrown. In about two years the rubbish in that part of the trench first filled, to the extent of about one-third of the whole, is thoroughly decayed, and therefore in a fit state for use. After being thrown out it is well mixed, all undecayed portions forked out, and then the mixture of vegetable soil and road grit (the latter comes off the paths) is worked into the strong heavy soil of the flower beds used with heavy soil when tree-planting, and is particularly good for stiff land intended for Potatoes. A few barrowloads of it are often useful in the frame ground and the potting shed should the ordinary leaf soil be scarce. The greater part of the grass from the mowing machines is taken to the farmyard, which I am inclined to think the best place for it. In some places it is given to the pigs, and is by them rapidly trampled into manure, and which is very effective on some soils.

The heap of kitchen garden rubbish is not buried, as it is not to lay unmolested so long, and is more easily prepared above ground. To this heap all the sweepings from the houses and the rough rubbish from the potting shed is wheeled. This is kept squared up as neatly as possible, and once a year—usually about this time—is turned over, the roughest portion being thrown out and burned; the ashes being stored away in a dry place, and are found of great service to the Carrot, Onion, and other crops. The heap of rich soil, which it must be admitted generally contains a great quantity of weed seeds, is usually distributed on the meadow land as an exchange for good fresh farmyard manure, which is employed first for hotbeds. If this exchange could not be effected I should unhesitatingly use the heap in the kitchen garden, as I do not believe in the possibility of growing good crops without a fair amount of manure, and during most seasons weeds can easily be kept down.

The third heap is composed principally of old soil from pot plants of all descriptions, with siftings and other rubbish from the potting bench. This mixture, when well broken up and cleared of any rough material, is in the spring freely employed for potting all kinds of summer bedding plants, and also proves almost invaluable in the frame ground. From the fact of its being rather light and sandy it is particularly suitable for early Carrots and Potatoes, and we also employ it with a little rougher soil added for Cauliflowers and Peas. After these crops are over much of it is again collected, and the next season is worked into naturally very stiff soil for early Potatoes and Carrots, to the great benefit of both crops.

I have been asked by gardeners at our local horticultural meetings how I managed to obtain such early Potatoes as Mona's Pride or Veitch's Improved Ashleaf of such good shape from the open ground. When informed that it is simply by freely using old potting soil the remark at once made was, "Oh! we haven't time for such coddling." Perhaps not, but at the same time I well knew that these men "coddled" with many things that neither my employer nor myself cared anything about. To have Potatoes fit to eat, and also good for exhibition, I here found it absolutely necessary first to bastard-trench the ground, and afterwards to work into the rows as much as possible of light sandy soil. The fact of having a large and good garden does not insure success. It is by attending to the smallest details that great things are accomplished. As it happens I have neither a large nor a good garden to manage, and what little I have achieved is partly owing to making good use of the soils obtained from the rubbish heaps. Call it "coddling" who will.—W. IGGULDEN.

BRUSSELS SPROUTS.—To produce the "best of Sprouts" ought the crown of the plant to be cut out or not? I find such diversity

of opinion on this point that I think the subject worth discussion in the *Journal of Horticulture*.—G. O. S.

PROPAGATING THE POTATO.

MESSRS. HOGG & ROBERTSON have sent us the accompanying woodcut, which represents an instrument that has been employed for the purpose of taking out the eyes of Potatoes with as small a portion of the substance of the tuber as possible, so that the remainder may be used as food. The following experiments with it were made by Jolliffe Tufnell, Esq., of Dublin, and by whom they were recorded in the *Irish Farmers' Gazette*:—"I purchased the scoop in question, and proceeded to the establishment of Messrs. Hogg and Robertson, Mary Street, and obtained from them a Rock Potato weighing 5½ ozs., and containing nine eyes. I scooped out each of the eyes, seven of which were good and strong, and two very weak indeed. The weight of these nine eyes amounted only to 1¼ oz.

"I took the eyes to the house of a friend—the Rev. Mr. Alcock, 38, Lansdowne Road, Dublin—and asked his permission to plant them in his vegetable garden, which he kindly granted, and they were set in good rich ground, as ordinarily manured with stable dung for the rest of his vegetables. They were put in a drill a foot from each other. Eight of these eyes vegetated and came up; the ninth (one of the weak ones) died. These eight plants received no further treatment in the way of extra covering with earth or any artificial manure. They were left to Nature, as any ordinary Potatoes, and dug upon the 23rd of October—that is, six months after planting.

"The result was as follows:—The total number of Potatoes under the eight stalks was 114, of these 52 were small, but many quite large enough for seed. Thirty-eight were table Potatoes of ordinary size, and thirteen very large, while only eleven showed any trace of spot or disease.

"This scoop, I afterwards learned from Mr. Henshaw, was never intended for the purpose to which I put it, but is simply what the cooks employ for scooping out pieces of Carrots and Turnips for soups."

Fig. 91.

PLANTS FOR HOUSE DECORATION.

PLANTS for house decoration, as well as those that are useful for cutting, are what most gardeners require. I have to supply large quantities for both purposes with but little convenience, yet I have been rather successful. I will now, however, only enumerate those plants which are useful at this season of the year. Bouvar-

dias Bridal Wreath, Vreelandi, and Maiden's Blush are valuable varieties, being so free in blooming. Cyclamens raised from seed sown in January will flower the following autumn, and if grown in a rather warm house and kept moist during the summer they will produce from twelve to eighteen or more blooms. Plants of *Solanum Capsicastrum* from early-sown seed, grown in pots plunged in good soil on a south aspect (which I prefer to planting out), will grow 18 inches high, as much in diameter, and be laden with berries. Chrysanthemums are extremely useful, the Japanese varieties being the best for cutting; Elaine is very fine, and flowers early. *Schizostylis coccinea* succeeds best if shaken out of the pots the plants have bloomed in, placing the largest in 9-inch pots; this is better than planting them out, as is generally advised. *Begonia fuchsioides*, *B. insignis*, *B. Saundersii*, and *B. ascotensis* should be grown to bloom through December and January with bulbs, Lily of the Valley, *Spiraea japonica*, *Plumbago rosea*, *Poinsettias*, the old white Azaleas, *Euphorbia jacquiniæflora*, *Linum trigynum*, and Zonal Geraniums. The last-named, if not allowed to bloom during the summer and grown in the full sun, will flower well during the winter months. *Calanthes* of the *vestita* and *Veitchii* section are also very useful. From Christmas onwards many of those enumerated will continue a supply of flowers. The Bouvardias, if kept in heat, will bloom through the winter. Forced shrubs and Roses may be had in succession till they come in naturally out of doors. Chinese Primulas come in well about this time. The old Solomon's Seal, if taken up, may be forced in a vinery just started; it is one of the most beautiful plants grown. Cinerarias are good for house decoration, but not for cutting. *Dielytra spectabilis* is useful if brought on gradually.

In most gardens there are abundance of plants and cut blooms during the spring; it is in the autumn and early winter that a scarcity occurs. All those named are well suited for house decoration. During the summer, show Pelargoniums, Fuchsias, *Campanula pyramidalis* and *C. calycanthema*, Lilliums, and Palms, are what we chiefly grow. I have omitted one plant which ought not to be passed unnoticed—namely, *Dendrobium nobile*, one of the most useful of Orchids, as it may be had in bloom with a succession of plants from November to June.—FLORIST.

THE UPTON NURSERIES.

FEW towns can boast of such celebrated nurseries as Chester. The old town has many attractions, but the most interesting to all true horticulturists are the nurseries, and among them that of Messrs. F. and A. Dickson & Sons. This is situated at Upton, about twenty minutes' walk from the railway station, and is approached on one side from Upton Park, and on the opposite side by the main road leading from the city to Birkenhead. This is the principal entrance, and has a lengthy, wide, and well-kept drive, on each side of which is a border 30 to 40 feet wide, which is planted at the end near the road with hundreds of very effective Golden and Silver Hollies. Following the Hollies right and left are thousands of choice Conifers varying from 2 feet 6 inches to 5 feet in height. Numbers of each variety are grouped together, and in the background are some fine specimens of *Araucaria imbricata*. Noticeable amongst the Conifers are *Cupressus Lawsoniana erecta viridis*, *C. L. gracilis*, *C. L. spica*; *Retinospora filifera alba*, *R. pisifera gracilis*, *R. plumosa*, and its beautiful golden form *R. plumosa aurea*, *Abies Englemannii*, *A. Menziesii* and others are very effective. This drive leads to the offices, packing sheds, and glass houses; but before reaching them the drive turns to the right, and at the left-hand corner a large quantity of *Thuja borealis* and its variety *compacta* are very conspicuous; they are fine specimens from 8 to 10 feet high. The border to the right is planted with specimen Hollies, *Picea nobilis* and *P. Nordmanniana*, *Wellingtonias* and choice shrubs, while the front of the border is made gay during the summer with bedding plants, and in winter with Daisies, Pansies, and others.

The glass houses are very extensive, forming one of the principal features of the Upton Nurseries. During the past few years much attention has been devoted to the glass department, and in few of the provincial nurseries is there so great an extent. New houses are built every year—a sufficient guarantee that the trade in this department is rapidly increasing. The first two houses are 90 feet long each and 9 feet wide filled with grafted *Cupressus*, *Thujas*, *Retinosporas*, *Abies*, Hollies, and choice Yews, with Tomatoes covering the roof, bearing an enormous crop of fruit, the variety grown being Dickson's Improved Trophy. A house 100 feet long is devoted to the propagation of Conifers, Rhododendrons, and Clematises; and another large house has recently been erected for specimens in pots. Three or four large houses are appropriated to Azaleas of the indica type, the majority in 6-inch pots. Numbers are worked in the nurseries on stems about

9 inches high, and others upon their own roots from bushy young plants. The back of a large half-span house is filled with specimen Azaleas of pyramidal shape suitable for exhibition purposes. Several large houses are devoted to Camellias, many in 6-inch pots. However, the chief stock varies in size from small grafted plants to others 6 or 7 feet high. Camellias, like the Azaleas, are largely worked in the nursery, and the plants are in the most robust health and studded with flower buds. Another house, 90 feet long and 16 feet wide, is devoted to Heaths of the *hyemalis* and *gracilis* type, and a number of *Libonias* well grown, and the variegated *Solanum Capsicastrum* is used as an edging, which, independent of its berries, is very effective. A fine lot of *Aralia Veitchii* and *gracillima* in the same house were sturdy and fine. When subjected to stove heat these plants soon become too tall for table decoration, but under cool treatment they remain of a suitable size for a long time. A long lean-to with a northern aspect is devoted to dwarf Ferns. There is also a good collection of hardy species and varieties. Other houses are filled with Palms, *Dracenas*, and *Crotons* suitable for decoration. The stove contains miscellaneous flowering and foliage plants, including Orchids in pots, and numbers in baskets suspended from the roof. A similar house is devoted to greenhouse plants, others for *Eucharises*, and numbers of heated span-roof pits are filled with Tree Carnations, *Bouvardias*, *Epiphyllums*, and other winter-flowering plants. The propagating house is 120 feet long, span-roofed, and is fully occupied with plants, some grafted, others just rooted, and thousands in process of rooting to keep up the stock. About three thousand Vines are grown in pots, and are clean, strong, and well ripened. A small house is devoted to fruiting some of the Vines annually, so that purchasers have an opportunity of seeing the fruiting qualities of the Vines.

The fruit trees alone are worth a long journey to see, as they cover about 40 acres. Pyramid Apple and Pear trees are excellent, and many of them in a fruit-bearing condition. Anyone with a knowledge of the rearing of young fruit trees cannot fail to admire their symmetrical shape. The horizontal and fan-trained Apple, Pear, Cherry, Peach, and Nectarine trees are equally good. A long, large, span-roofed house is devoted to pyramidal Peach and Nectarine trees in pots; the wood is well ripened and in capital order for forcing. A large cool pit is also filled with Figs in pots.

Roses are another great feature, and several houses are devoted to Tea and Noisette varieties upon their own roots and worked upon the seedling Briar. About ten thousand are annually raised, and one house is full of *Maréchal Niel*; *Gloire de Dijon* and others in 8-inch pots have made a growth of 15 to 20 feet, and are quite suitable for forcing. Some three thousand strong Hybrid Perpetuals are grown in the same size pot and for the same purpose. About sixty thousand standards and two hundred thousand dwarfs are grown upon their own roots, the *Manetti*, and seedling Briar. The whole stock is remarkable for the luxuriance of the plants.

In the front of the principal houses is a geometrically designed flower garden, which is kept gay during summer with suitable plants, and in close proximity are two fine specimen Irish Yews. On each side of the walk is a border planted with new and rare Conifers, principally golden and variegated forms, *Thujaopsis argentea variegata*, *Juniperus chinensis aurea*, a beautiful golden fern; and *J. c. japonica alba variegata* are conspicuous. This border also contains many choice standard Hollies and Yews, and at the end is a magnificent piece of artificial rockwork. Near to the houses is the collection of herbaceous plants, including all the chief forms in cultivation, and also alpine plants, which are principally in pots, and number about twenty thousand.

Acres of *Rhododendron ponticum* and *Azalea pontica* are grown, and hundreds of handlights are employed for raising seedlings of the former. The seed is sown in a large frame close to the glass, and the young plants obtained are pricked out under the handlights in long narrow beds 3 feet wide, with a row of bricks each side for the frames to rest upon. Hybrids are grafted in considerable numbers, and the stock is large and good, as only the best are grown. A very large square of ground is devoted to the stock plants, and at one end is a magnificent specimen of *Araucaria imbricata* fully 30 feet in height. *Cedrus Deodara* is grown in large numbers, and some very fine plants are noticeable; they are very compact and thick, being pruned with the knife every spring. The thousands of *Ivies*, *Ampelopsises*, *Clematisses*, and other climbing plants grown is surprising; all are in pots and plunged. The stock plants of the *Clematisses* occupy a large span-roofed pit, which is a great advantage for obtaining wood early for grafting purposes. Many other plants, such as *Cotoneasters* (*Simondsii* is a handsome species for shrubberies), *Arbutuses*, Evergreen Oaks, *Escallonias*, *Euonymuses*, *Cistuses*, and *Ceanothuses*, and similar plants are kept in pots and plunged, which facilitates

their safe removal. The labour in this department is enormous, as these plunged plants cover several acres of ground.

Much attention is given to Conifers, and many acres are occupied with plants of various sizes, and in addition to the houses already mentioned almost innumerable frames and handlights are employed for their propagation. The cuttings are thickly inserted under them, and when rooted all are placed in pots until established, and are then finally planted out. Hollies are propagated on the same large scale, and the stock is large and good. The variety *Hodginsii* is more largely grown than any other; it is the best and hardiest Holly, and will stand uninjured in smoky exposed districts where the common Holly fails and dies. Yews, *Aucubas*, common and Portugal Laurels, *Berberises*, *Laurustinuses*, *Privets*, and evergreens are grown in large breadths containing many thousands of bushy plants of each. Flowering shrubs, such as *Deutzias*, *Weigelas*, *Spiræas*, *Syringas*, and *Ribes*, are grown in equally large numbers; the latter, red and white, are grown as standards, and are very effective when in flower.

The forest department is an extensive one, and acres of ground are covered with seedlings of Larch, Spruce Fir, Scotch, Austrian and Corsican Pines; the last is one of the best for planting at the seaside. Some millions of each are grown. Standard Horse Chestnuts, Elms, Oaks, Ash, Maples, Beech, and many other ornamental deciduous trees are grown of all sizes and thinly planted, so that they may develop naturally. This is noticeable throughout the nursery; every shrub and fruit tree has ample room. The soil varies considerably throughout the nurseries; in some parts it is of a strong tenacious nature, in others light and sandy.

It would require too much of your valuable space to attempt a notice of everything of interest in nurseries of such extent and magnitude, and it is only necessary to add that the whole nursery is very clean and the stock well grown. About 170 acres of ground form the nursery, and the extensive seed warehouse is situated in Eastgate Street.—WM. BARDNEY.

ABOUT CUT FLOWERS.

THE continuous supply of cut flowers is of great importance in the routine of gardening. Public rooms, bedrooms, boudoirs, and chapels are considered incomplete unless furnished with cut flowers. The period between the disappearance of the last of the Michaelmas Daisies and the advent of Snowdrops, Christmas Roses, and Winter Aconites has to be provided with as many flowers as during the most floriferous months of the year. Producing flowers and utilising them to the best advantage is, consequently, of great importance. To have flowers during a few weeks in abundance, then for a period be very scarce, is not good management; it is better to have only a small overplus and a continued supply. There is not much practical use at this time of the year in advising as to the management of plants for a winter's supply. A few notes on cutting and preserving flowers will be much more beneficial to those who are inexperienced.

The proper stage at which to cut flowers for decoration is the most important part of this subject of flower supply next to the production. A rule which I invariably follow is this—Never cut any flowers until fully developed. Flowers which open when cut, as the *Gladiolus*, may be exceptions to this rule, but trusses of *Pelargoniums* and *Bouvardias* should not be cut until fully developed. Nor is this all. Flowers are allowed to remain on the plants as long as they will continue in good condition. To gather a bloom which would last for a week or two, and pass over a bloom which would be useless in a few days, is disadvantageous in two ways. In the first place the young bloom is sacrificed at a time when it is not needed and the older bloom is entirely wasted. This system will in a short time change a sufficient quantity into scarcity. Another matter can only be settled by experience, and that is cutting more flowers than are required at one time. It is also quite possible to use very many more flowers in decorating vases than are necessary, to the detriment of the flowers, which invariably last longer when thinly arranged. Every flower ought to stand entirely clear of its neighbour. I effect this by employing foliage freely, filling large glasses with foliage, and then inserting the flowers. Water is always used, as being most cleanly and keeping the flowers in good condition for a longer period than any other medium.

For some time past flowering shoots of Ivy have been placed in the largest size glasses, the heads of Ivy flowers and many of the leaves showing above the other flowers. *Pteris tremula*, *P. longifolia* and *Davallia Mooreana* are very suitable for glasses of a very large size. The common Yew and the finer ornamental class of evergreen trees are useful after the Ivy is past. A glass arranged to-day was thickly filled with flowering shoots of several *Begonias*, amongst which were trusses of white and red *Bouvardias*. Another

of similar size was filled with the foliage of Pheasants'-foot Pelargonium, the flowers being scarlet Pelargoniums and sprays of Aster turbinellus. Small low glasses have a single truss of Pelargonium with a large leaf for setting. Camellias with their foliage, also Chrysanthemums, are much used at this season for the same kind of glasses. Large glasses can be very effectively filled with four or five Richardia blooms set on their own foliage, and a few Pelargonium trusses or red Bouvardias added to impart colour. Glasses filled with Mignonette require only a very few good flowers to give a finish. Good-sized glasses can be filled exclusively with Chinese Primroses set in their own foliage. Tulips may also be used by themselves with their leaves. Cyclamens never look so well when associated with other flowers as they do by themselves with their foliage. The spikes and foliage of Lily of the Valley make a most chaste arrangement. Violets should always be arranged by themselves, so should Roses if there is a sufficient number of them to work on. Of course these can all be worked up in mixed arrangements with other flowers, such as Orchids and other flowers which do not make effective bouquets alone. But wherever the foliage of a plant and its flowers go well together they ought to be occasionally employed in that way. The harmonising and contrasting of colours is also a question of some importance, but in this the varied tastes of employers have in a great degree to be studied. White flowers and the few yellow ones that may be used do well with any colour; dark blue or purple flowers are not suitable at this season; pink shades are best with white or yellow flowers.

All flowers, Ferns, and foliage should be cut with the longest possible stems. I do not strip the leaves off flower stems and Ferns, more especially Maidenhair Ferns; I also have a portion of the fronds inserted in the water. These last much longer for various purposes if cut and placed for two days in water before using. In hot rooms the glasses require periodically filling. When the flowers are freshly arranged the glasses should be washed before being refilled. Many flowers last a long time at this season, such as Cyclamens, Pelargoniums, Orchids, and others; these should never be left longer than three or four days without having fresh water and being re-arranged.—R. P. BROTHERSTON.

At the annual general meeting of the NATIONAL AURICULA, CARNATION, AND PICOTEE SOCIETIES, held on the 28th ult., it was decided to hold the Exhibition for 1881 under the auspices of the Royal Horticultural Society. The Auricula Exhibition is to be held on April 19th; the Carnation and Picotee on July 19th. The annual report and balance sheet for 1880 was adopted by the meeting, the Treasurer's statement showing a balance in hand for the Auricula Society of £10 15s. 1d.; that of the Carnation and Picotee, £36 8s. 11d. Additional prizes have been added to some of the classes, and a new class is added for yellow-ground Picotees.

— THE ROYAL CALEDONIAN HORTICULTURAL SOCIETY will, it is announced, hold the following exhibitions in 1881. The spring show on April 6th and 7th, and the autumn show on September the 7th and 8th.

— IN addition to the white sport from JAMES SALTER CHRYSANTHEMUM shown at the Brixton Exhibition, a competitor (Mr. H. A. Rolt, Wimbledon), at the Kingston and Surbiton Society's Show had also a white sport from James Salter. Whether these forms can be perpetuated remains to be seen, but if they can be fixed the variety will soon become as established a favourite as the one from which it originated.

— WE understand that the CANTERBURY ROSE SHOW is fixed for the 30th June, under the presidency of the Marquis of Conyngham, and that a schedule as liberal, if not more so, than that of the present year will be arranged. The Society is a prosperous one, and we hope will continue to be so.

— WE learn with pleasure that the Royal Caledonian Horticultural Society has awarded the NEILL PRIZE for the biennial period 1878 to 1880 to Mr. David Thomson, gardener to the Duke of Buccleuch, Drumlanrig, as a distinguished horticulturist. Our readers may remember that this prize, which is so highly valued by Scottish gardeners, is derived from a fund left for the purpose by Dr. Patrick Neill of Cannonmills Cottage. He bequeathed £500, the interest of which was to be allowed to accumulate, and be awarded every two or three years by the Royal Caledonian Horticultural Society as Trustees, to a distinguished Scottish botanist or horticulturist. The Society's choice will on this occasion undoubtedly meet with general approval.

— A CORRESPONDENT, in a report that arrived too late for publication, states that FRUIT AT THE SHREWSBURY SHOW was remarkably fine. The successful competitors in the class for black Grapes were Mr. Hannagan, gardener to R. C. Naylor, Esq., Hooton Hall, Cheshire, and Mr. Milner, gardener to the Rev. J. W. Corbet, and Mr. Boody, gardener to Viscount Boyne. For white Grapes Mr. Breese, The Gardens, Moreton Hall, Cheshire, Mr. Lambert, gardener to C. G. Wingfield, Esq., and Mr. Pratt, gardener to Lord Hill, were the prizetakers, all with superior produce. Mr. Pratt had the chief prize for a Pine Apple. Mr. Young, gardener to Sir Henry S. Stanhope, Bart., Holme Lacy, was awarded the first prize for a collection of Pears, thirty fine dishes, also for twelve and six dishes of Pears, and the same number of dishes of Apples. Mr. Rite, gardener to A. Maw, Esq., Severn House, Tonbridge, Mr. Lambert, and Mr. Bain, gardener to Sir C. R. Boughton-Knight, Bart., Downton Hall, Ludlow, were the other prizewinners in the same classes. Messrs. Juson, Abbey, Forgate, and Pratt were among the most successful exhibitors in the Chrysanthemum classes. The Show is described as one of great excellence and admirably managed throughout.

— MR. ABRAM BASS has sent us some specimens of APPLES GROWN UNDER GLASS at Moat Bank. The Cox's Orange Pippins are the finest we have seen this year and of superior quality. Kedleston Pippin is also splendid in appearance and of good quality, the Ribstons having passed their best condition. Mr. Bass states that the only Apples that have not improved by being grown in an orchard home are the variety last named and Nonpareils.

— IN the corridor near the large conservatory at the Royal Botanic Society's Gardens, Regent's Park, there is now a pleasing display of CHRYSANTHEMUMS IN POTS, the plants being healthy, the varieties well selected, and the blooms generally of good form and substance, though, not, perhaps, up to the exhibition standard. The specimens are not formally trained but allowed a considerable degree of freedom, the number of blooms being sufficient to produce a very satisfactory array of colours. A number of thoroughly good varieties are represented, among which the following are especially notable for their excellent condition—Golden George Glenny, Queen of England, Guernsey Nugget, Antonelli, Lord Derby, Mrs. G. Rundle, and the Japanese varieties La Nympe, Elaine, Gloire de Toulouse, Fulton, and Red Dragon.

— AT THE DUBLIN ROYAL HORTICULTURAL SOCIETY'S AUTUMN SHOW, held on the 25th ult., Apples, Grapes, and Chrysanthemums are stated by the *Irish Farmers' Gazette* to have been very fine. Mr. Lombard's first-prize dish of Warner's King Apple weighed nearly half a stone, one fruit weighing 21 ozs. The Countess of Charleville, Charleville Forest, Tullamore (gardener, Mr. Roberts), secured the chief prizes for Grapes with splendid produce—he also exhibited a bunch of black Grapes weighing 1½ stone, for which the Society's medal was recommended; L. Lepoy and T. P. Hogg, Esq., for Pears with Marie

Louise, Huyshe's Victoria, and others; and Charles Cobbe, Esq., for Apples, Cox's Orange Pippin being very fine. Chrysanthemums were well represented, particularly the cut blooms. For large-flowered varieties Francis Low, Esq., Avonmore, Stillorgan (gardener, Mr. Gough), and Alexander Comyns, Esq., Ardcuaine (gardener, Mr. Jenkins), obtained the chief prizes with good collections; the latter secured the chief award for Anemone-flowered varieties, followed the Rev. Frederick Tymons (gardener, Mr. McKeogh) with a collection of Poms.

— A CORRESPONDENT sends the following note concerning the EXHIBITION OF CHRYSANTHEMUMS AT MANCHESTER. The autumnal Exhibition in connection with the Botanical and Horticultural Society, Old Trafford, was opened on Tuesday the 23rd ult., in the Town Hall, Albert Square. The display of Chrysanthemums was the main feature of the Exhibition, as, owing to the inclemency of the weather, many delicate plants, which would otherwise have been sent to add to the beauty of the Show, were kept in the greenhouses. The collection exhibited by Mr. C. S. Agnew included thirty specimen Chrysanthemums bearing blooms of unusual size. Many of the flowers were from 15 to 18 inches in circumference. The plants from the Botanical Gardens, which consisted of about 250 Chrysanthemums, were arranged upon the platform and around the organ in a very effective manner. The other exhibitors were Mr. G. F. Lee of Timperley, Mr. Crompton Potter of Rusholme, and several nurserymen. The gold medal of the Society was awarded to Mr. C. S. Agnew of Eccles Old Road. Cultural certificates were given to a group of Chrysanthemums exhibited by Mr. John Rylands of Stretford; and to G. & W. Yates of Stockport. Messrs. Dickson, Brown, and Tait were awarded certificates of commendation for Cyclamens and Roman Hyacinths; Mr. G. F. Lee and Mr. Crompton Potter obtained a similar honour for displays of cut blooms of Chrysanthemums; while Messrs. Dickson, Brown, & Tait were commended for a show of miscellaneous plants.

— AT Hackney, too, Messrs. S. Dixon & Co. have in the AMHERST NURSERIES a fine collection of Chrysanthemums, including many of the newest varieties. The Japanese forms are particularly noteworthy, the examples of the distinct and attractive Mons. Crousse, Nuit d'Automne, Arlequin, Lutea striata, and Fleur d'Hiver being excellent.

— Mr. B. E. JAMES sends us the following note on the BRISTOL EXHIBITION OF FRUIT AND PLANTS held last week—"The Chrysanthemums formed the chief feature of the Show, and were uncommonly fine both in the health of the plants and the size of the blooms. Mr. Bradner of Bristol was the chief exhibitor, and carried off the principal prizes. Messrs. J. Garraway and Co., Durdham Down Nurseries, also exhibited largely, taking many prizes, and the Knightian medal offered by the Royal Horticultural Society. Miscellaneous collections of plants were numerous and good, while, although Pears and Apples were not very abundant, they were represented by several good collections."

— LAST week two correspondents obligingly sent us reports of the GRAVESEND AUTUMN EXHIBITION that, however, arrived too late for insertion. The following briefly indicates the chief features of the Show, which was held in the Milton Hall on the 17th and 18th ult. Chrysanthemums formed the most imposing part of the Exhibition, though fruit and vegetables were also well represented, and the entries in all classes showed an improvement over last year. In the chief class for four dwarf-trained specimen Chrysanthemums the prizetakers were Mr. R. Lambkin, gardener to J. S. Dismore, Esq.; Mr. Phillips, gardener to Capt. Jackson, Meopham; and Mr. Hollman, gardener to the Rev. Lewis, The Vicarage, Meopham; these exhibitors also carrying off several other prizes for plants. Cut blooms were good, Messrs. Phillips; Hollman; G. Pendred, gardener to C. Umfreville, Esq.; and

W. Etherington, gardener to R. Stewart, Esq., Swanscombe, securing the principal prizes; while in the fruit classes Mr. J. Wright, gardener to C. Bryant, Esq., Gravesend; Mr. Pendred; and Mr. T. Richardson, gardener to Sir James Ferguson, were the most successful. The Committee, which is wholly composed of gardeners, may be congratulated upon their satisfactory management. Another correspondent kindly forwarded a report of the Northampton Chrysanthemum Show, which also unfortunately arrived too late for insertion. The Exhibition is stated to be one of the best that has been held by the Society, the exhibits being numerous and of good quality.

MANCHESTER FRUIT AND VEGETABLE MARKETS.

(Continued from page 443.)

CARROTS first appear in the market in April; they come from France in bunches. About the first week in June they begin to arrive from Holland, also in bunches. Then come supplies from Bedfordshire. Towards the end of August large supplies come loose in trucks from Lincolnshire and Huntingdonshire, increasing in quantity as the season advances. The rate for bringing them from the last three places mentioned is from 11s. 8d. to 13s. per ton.

The Turnips supplied to the market for culinary purposes are grown almost exclusively within a few miles of it. They consist of three sorts. First, a very excellent variety raised by Mr. James Kelsall, late of Stretford, now of Picton Gorse Farm, near Chester, about fifteen years ago. During the winter two yellow kinds are most in favour—the "Orange Jelly," brought out by Messrs. Dickson & Brown, the eminent seedsmen of Chester, and the "Scarisbrick Yellow." The "White Stone," generally seen in the south of England markets, finds no favour here.

Forced Rhubarb makes its first appearance in the market in Christmas week. As the spring advances the supply increases, and large quantities are sold. A great deal is grown in this locality; but the largest quantity and the finest quality that comes from any one place is grown by Mr. Joseph Whitwell of Kirkstall, near Leeds. Mr. Whitwell has made its cultivation a speciality. The forced is succeeded by an abundance of the naturally grown, nearly every gardener who comes to the market contributing a portion. Thirty-five years ago the late Mr. Samuel Osbaldiston of Baguley was almost the only person who brought Rhubarb to the market. He grew the kind known as "Myatt's Victoria;" there was then an intermittent supply of the dwarf red kind, grown upon Preston old racecourse. But Mr. Osbaldiston was undoubtedly the first who brought Rhubarb into the Manchester market, and he also claimed a similar honour for Strawberries.

Vast quantities of green vegetables are grown in and about Stretford, where the land is very highly cultivated, for this market; and in Stretford and the adjacent parishes of Ashton-upon-Mersey, Sale, Baguley, and Timperley many Strawberries are grown. Apples, Pears, and Plums were formerly plentifully grown about Stretford; indeed, forty years ago there were no more fruitful orchards north of the Trent, but the same city which has contributed so much to the wealth of the owners of the soil around it has, with its polluted atmosphere, made sad havoc with their trees, which now "but cumber the ground," and consequently are fast disappearing under the axe to make way for the growth of things more profitable.

Celery usually makes its first appearance in the market about the second week in July. It is grown extensively upon the moss land in the parish of Ashton-under-Lyne, and is the variety known as "Lady White." This is followed by the "Seymour White," grown principally about Sale, Ashton-upon-Mersey, and Timperley; and next comes a supply from the neighbourhood of Retford in Nottinghamshire, which is called the "Grove-red." A considerable quantity is also sent from Lincolnshire. From the two last-mentioned places the supply lasts into April.

English Onions are chiefly supplied from Bedfordshire. From August to May there are frequently from 60 to 80 tons sent to Manchester from that locality in one week. The carriage costs from 18s. 4d. to 20s. per ton. Between July and April large quantities come from Holland; rates for carrying about 23s. 4d. per ton.

From September to June there are heavy arrivals from Germany. The lowest rate for bringing them is 26s. 10d. per ton. When brought from the most distant part of that country the rate is as high as £5 per ton. Of course such importations can be made only when the price is very high.

Arrivals of Belgian Onions are in their plenitude during August

and September; rates about 20s. per ton. From October to January Bordeaux sends us a considerable quantity. They are shipped in cases of about 1 cwt. nett. Cost of carriage, 2s. 1d. per case. During May, June, and July the supplies are from Portugal; and in the same months, on a limited scale, from Malta and the Levant. Rates from Liverpool 7s. 6d. per ton.

Cucumbers here not inappropriately follow Onions, and for the additional reason that, like that useful and popular bulb, they are grown chiefly in Bedfordshire. They are planted in fields of large extent, and no artificial heat being used they are not ready for the market until August, when they soon become very plentiful, and consequently exceedingly cheap. From 100 to 120 tons per week are in good seasons poured into the market, and on such occasions they are sometimes retailed at four a penny.

The English early Cucumbers always fetch a good price up to about the end of May, when they have to compete with importations from Holland.

Without separately mentioning every kind of vegetable, suffice it to say that all and every kind of herb that has come into ordinary use is plentifully and cheaply supplied to the vast community of these districts through the great central market at Manchester, and that not only does the supply diligently wait upon the demand, but by the enterprise of the British growers and the importers the supply occasionally creates the demand!

I am bound to say, however, that in speaking of "the enterprise of the British growers" I refer more particularly to those at a distance; and I trust my rural friends, the market gardeners and farmers of this locality, will not think me presumptuous and that I am travelling out of my province if I express the opinion that they are somewhat slow in discovering and supplying many of those things which are most remunerative to the grower. For many years they permitted the more heavily rented growers in the vicinity of London, who were handicapped with the cost of bringing it two hundred miles to market, to supply us with Rhubarb. It is within my own recollection that not a single Cos Lettuce, the only sort fit to be eaten, could be obtained in Lancashire but what came from beyond London, and for many years no one here attempted to grow these things; now everybody grows both. Probably nothing is more easy to grow than Scarlet Runners, and nothing finds a readier sale in the Lancashire markets. I have seen them sold this year at 8s. a bushel, but they came from a distant part of the country, the local gardener or farmer at the same time bringing a cartload of Cabbage, which sold for very little more. Brussels Sprouts are also eagerly sought for here, and bring 2s. or 3s. a peck; but the local grower of vegetables says, as he once said of Rhubarb and Cos Lettuce, "I cannot grow them," notwithstanding that few things are as hardy. A Stretford gardener's excuse for not growing Brussels Sprouts, as given to me, was "The land about my neighbourhood is too rich." Well, when we see so many fields in Cheshire whose principal crop is Rushes we certainly cannot allow the farmer or gardener who occupies them to plead the same excuse. The cost of bringing these heavy commodities from a long distance is great, and should be, if not a "prohibitive duty," at least a "protection" to the local grower, to say nothing of him being enabled to bring his goods to market in a fresh condition. Besides, the words "my own growing" have a magical effect, and seldom fail to secure the preference of the purchaser; indeed, so much are these words valued by the seller—and abused—that I once heard them used by a fellow selling Cocoa-nuts!—(*Royal Agricultural Society's Journal*).

TREE PLANTING.

OFTEN as I have written about tree and shrub planting, I am convinced it is necessary to say still more on the subject, and as the planting season is approaching I cannot perhaps say it at a better time than now. Patient repetition is undoubtedly a teacher's forte, and it is only by doing so in as varied and attractive a manner as possible that he can hope to enforce lessons hard to learn. In this instance the art of tasteful combination appears to be the hard lesson. We have not far to seek for the reason. Go into a nursery garden, large or small, during the planting season, and the eye is at once caught and fixed by Conifers and evergreens, to which a prominent position is always given. Do they not afford us symmetry, elegance, richness, warmth, and above all infinite variety of form and colour? What more do we require? And so the order is given to the exclusion of deciduous trees, and the garden to be planted lacks a charm for which nothing can atone. It is true that in winter we are grateful for the richness and warmth of our evergreens, but beautiful as they unquestionably are, and great as is their intrinsic worth, yet they gain much in effect when associated with deciduous trees, even in

winter; but in spring time, when "bursting leaflets clothe each spray," and all the brightness and freshness of vernal beauty comes back to us once more, deciduous trees develop attractions that grow upon us daily till they culminate in the full splendour of summer in "leafy June." Nor must we forget the rich autumnal tints of the decaying foliage which, beautiful as it is and admired for itself, gains much by association with the feathery forms and soft shades of green of the Conifers.

Is the force of contrast among trees fully recognised? If not, the planter can hardly hope to turn his work to the best account. It is a matter demanding careful study combined with refined taste, for startling contrast is as objectionable as tameness and insipidity. To reduce theory to practice, let us proceed to a selection of a few of our best trees for planting in combination.

Of Conifers we may take *Pinus insignis*, always attractive from its bright-toned green foliage and its dense yet free growth. *Pinus excelsa*, the Himalaya Pine; of free growth, but not so dense as *insignis*, to the rich green of which its long, drooping light-coloured foliage offers a fine contrast. *Taxodium distichum*, the charming deciduous Cypress; an elegant cone-shaped tree, with the branches and stem quite hidden in summer with foliage of a singularly soft feathery aspect, and peculiar shade of green. *Picea cephalonica*, bearing a general resemblance to the Spanish *Picea pinsapo*, but altogether of a bolder type; very ornamental, and quite distinct from any of our present selection, to which two more *Piceas* must be added—*P. pectinata*, the well-known Silver Fir, often now classed with forest trees, but none the less valuable for a place among our choicest ornamental trees, and *P. Nordmanniana*, the most elegant of all the *Piceas*, growing quite as fast as *P. pectinata*, and like it, too, in gaining beauty with increasing size. *Abies Morinda*, the beautiful Himalaya weeping Spruce, is the only one of its section suitable for our purpose; it forms a stately tree in this country, and its pendent branches impart a singularly graceful air to it. *Abies Douglasii* must also have a leading place as a prime ornamental tree, already upwards of 100 feet high in this country, the tallest of all the Hemlock Firs, forming a charming cone of soft feathery green, quite devoid of stiffness or formality. *Abies canadensis*, though not so tall, tells well in the front ranks of a clump, and is remarkable for its elegant, slender, pendulous branches. *Araucaria imbricata* growing freely in both light and heavy loams, but best of all in soil containing a plentiful admixture of fine charcoal; *Cedrus atlantica*, a lofty and fast-growing tree; the common Larch; and the Scotch Fir (*Pinus sylvestris*).

There are many other fine Conifers worthy of a place, but I have taken only those of proved excellence and of distinct appearance in order to render the selection really useful; all of them are evergreen except the Larch and *Taxodium*. Of other deciduous trees of a sufficiently bold type to blend well with them take the common Beech (*Fagus sylvatica*), the Purple Beech (*F. purpurea*), *Fraxinus excelsior* (the common Ash), to which not half enough importance is given as an ornamental tree, and yet its tall growth and beautiful foliage render it both conspicuous and attractive; the Turkey Oak, Fulham Oak, Lucombe Oak, Scarlet Oak, and Common Oak, all grand ornamental trees in deep loams, but often the reverse in shallow soils; *Platanus orientalis*, the Plane so much used in London, and which makes a fine lofty tree in a thin soil overlying a mass of sandstone; *Liriodendron tulipifera*, the Tulip Tree, with bold, handsome foliage and of lofty growth; the common Robinia *Pseud-acacia*; the common Lime, valued throughout the season of growth for its dense clothing of foliage, and in early summer for the sweet perfume of its flowers; Spanish Chestnut, Horse Chestnut, Birch, wild and double-blossomed Cherry, scarlet Maple, Sycamore, and Weeping Beech. The Weeping Beech is a grotesque object, only admissible into our clump as a foil, which by force of contrast imparts a charm to the most beautiful trees. To be quite accurate I should add that Lucombe and Fulham Oaks are not strictly speaking deciduous trees.

With the exception of the Weeping Beech every one of these trees is worthy of a place as a specimen. Nor need they be so much crowded in a clump as to lose their individuality. Have plenty of nursing Larches at first if you will, but plant the permanent trees from 50 to 80 feet apart, give due and prompt attention to thinning, and so will they slowly but surely develop all their charms.—EDWARD LUCKHURST.

MELON CULTURE—THE BLENHEIM ORANGE.

THE many inferior and insipid Melons so plentifully met with induce me to offer a few remarks on the culture of this fruit. I do not believe the cold frame treatment suitable for producing good-flavoured Melons, not having yet met with an example

worthy of the name grown under such conditions; but of course with the assistance of fermenting materials to heat the frames success is easily attained in summer. For early or late work hot water is preferred, as fruit of full flavour is only attained by a plentiful supply of fresh, dry, and warm air during the ripening process; hence the utility of the pipes to keep up the requisite temperature. The reverse of this is the principal cause of the flavourless samples so often met with. Until the fruit approaches the ripening point plenty of atmospheric moisture is necessary with a temperature of 70° to 80°, otherwise red spider and other insects will give much trouble, as they would also destroy the chances of securing high flavour. Most growers have their favourite varieties, but I cannot too strongly recommend a trial of the Blenheim Orange, as I am of opinion its sterling merits

will soon establish it as one of the leading Melons, and a first favourite with amateurs. It originated by crossing Hero of Bath with Read's Scarlet-flesh, and possesses the distinct markings of both parents, with an extraordinary depth of orange scarlet flesh. Its constitution is good, the plants being fairly robust, showing and setting their fruit freely. It is beautifully netted and handsome in appearance, and is well adapted for early forcing, as it ripens in a comparatively short space of time. Several practical judges have pronounced it to be the best flavoured Melon ever brought before them, and grand for exhibition.—W. CRUMP, *Blenheim*.

[We are indebted to Messrs. James Carter & Co. for the annexed engraving from a photograph of this excellent Melon, one fruit of which is enlarged and truthfully represented. This Melon

Fig. 92.—BLENHEIM ORANGE MELON.

received the first prize at the great Show at South Kensington on June the 8th, when thirty-one fruits were staged in competition. A first-class certificate was also awarded for it by the Fruit Committee of the Royal Horticultural Society on September 14th of the present year.—EDS.]

WORK FOR THE WEEK.

KITCHEN GARDEN.

AMONGST matters that may be attended to when the ordinary routine is interrupted by snow or other unfavourable weather may be mentioned the preparation of Pea-sticks, stakes in suitable sizes for various purposes, pegs for layering, and twigs for laying-in the young growths of Peaches, Nectarines, and Morello Cherries. The trimmings of Privet hedges are the most suitable; they should have the leaves stripped off, be tied in bunches to straighten, and be then placed in a dry situation to harden. Roots in store houses should have attention, and particularly Potatoes of early varieties intended

for planting in the ensuing season. Place the sets, as soon as suitable space is at liberty, in a single layer to prevent the destruction of the first growths, and to keep the sprouts as sturdy as possible. The position must be cool, but exclude frost. Remove decomposed material from pits to where it is required. Manure ground that is rather strong and intended for spring crops, but where the soil is very light or gravelly manure is better applied in the early part of the year before the crops are planted or sown. Attend to the accumulation of vegetable matter from the garden or elsewhere, taking the opportunity afforded by frosty weather to throw it into a ridge-like heap and intermingling about a sixth of quicklime, which if again turned in spring will form an admirable dressing for lawns and vegetable crops generally. Where ordinary care has been exercised in this direction much valuable material will now be fit for application.

MUSHROOM HOUSE.

Continue preparing successional beds, and as the temperature is now much reduced naturally the beds should be made thicker or

deeper, and the material be employed in a fresher and rather moister condition than early in the season. Rendering the bed thoroughly firm is of primary importance in the culture of this esteemed edible; next, the insertion of proper and good spawn when the bed is at a temperature of about 75°, a few degrees over rather than under, covering with rich turfy loam, and maintaining an equable and suitable temperature. Placing straw or hay over the bed after earthing-up will do much to secure a favourable condition both as regards moisture and temperature, but those materials must be removed as soon as the Mushrooms appear; when, if there be any deficiency of moisture, apply sufficient tepid water to render it moist but not saturated. Beds in bearing will also need to be kept damp, avoiding as much as possible applying water directly over the Mushrooms. Houses in which artificial heat is employed will require to have the walls and pathways, &c., damped frequently, maintaining the temperature between 55° and 60°. Slugs must be sought at night and destroyed; woodlice may be trapped by wrapping a boiled Potato loosely in a little hay placed in a flower pot laid on its side. Examine it every morning, and shake out the pests in a bucket of boiling water.

FRUIT HOUSES.

Vines.—To obtain ripe Grapes before the end of May forcing must now be commenced in earnest. Start with a night temperature of 50° and 55° in mild weather, but do not exceed this till the buds are growing. Syringe the rods two or three times a day, but if a bed of leaves and stable litter has been placed on the floor or border of the house, and a portion is stirred daily, a moist atmosphere will be maintained without frequent syringing. The outside border must have the needful protection from cold rain and snow, and heat may be afforded by means of litter and leaves, one part of the former to two of the latter. Borders that have been covered with straw or bracken and protected from wet will not need any other aid. The inside border should be made thoroughly moist with water at 80° to 90°. Allow the temperature to advance to 65° from sun heat, above which ventilate freely. Vines in pots that were started some time ago should have the temperature gradually increased to 60° at night when they are in leaf, 65° in the day artificially, and 70° to 75° from sun heat, admitting a little air at 70°, and if the temperature rise to 80° after closing it will lessen the necessity for fire heat. Vines in midseason houses should ere this have been pruned and at rest. The houses may be full of plants, which will not do any harm provided they are not kept warm. Whilst Vines are at rest it is only necessary to exclude frost.

Figs.—The fermenting materials for the trees in pots must be watched to see that the heat does not exceed 75°, and before introducing fresh material to keep up the required level it should be thrown into a heap and turned over once or twice. Allow the trees to advance steadily in a moist genial atmosphere, not exceeding 50° at night or 55° on mild nights, with 10° to 15° rise by day. When the leaves are showing the night temperature should gradually be raised to 55° or 60°, 65° by day artificially, and 70° to 75° from sun heat. A little ventilation should be given at the top of the house, from 65°. Syringe the trees two or three times a day, and if the weather be very cold and necessitating good fires moisture must be provided at night by damping the paths at about 8 P.M. There should not be any deficiency of moisture at the roots, and the water supplied must not be lower in temperature than that of the bed. Push forward the cleaning and dressing the trees in later houses. Trees at rest must not be allowed to become dust dry at the roots, but should have water as needed to keep the soil moderately moist.

Cucumbers.—Snow, sharp frosts, cold and keen winds have characterised the weather for some time, rendering the progress of Cucumbers very slow. A suitable and even temperature is of first importance towards success, especially at night, which is not always attainable without increasing the fires and producing an excessively dry atmosphere. Much may be done to prevent this by covering the houses with mats at night. A temperature of 60° to 65° at night is suitable, and 70° to 75° by day. Be moderate in the application of moisture at this season; damping available surfaces morning and afternoon will usually be sufficient. Water must be copiously supplied when necessary. Avoid overcrowding and overcropping, encourag-

ing the roots with fresh compost as they protrude through the sides of the hilloeks. Make the compost moderately firm, and give weak liquid manure occasionally. Continue removing old foliage and exhausted growths, but do not stop very closely for the next two months. Remove all tendrils and male blossoms from the winter-fruited plants, and encourage the swelling of the fruit.

PLANT HOUSES.

Orchids.—*Dendrobium moniliforme*, *D. nobile*, *D. Ainsworthi*, and *D. Dominianum* that have completed their growth early, if now placed near the glass in the East Indian house, will flower very usefully; but they must not be kept too moist, or they will start into growth. Where it is necessary to retard the flowering of *Dendrobiums* until May they should be placed in a greenhouse temperature and receive very little water, if indeed any; but the pseudobulbs must not be allowed to shrivel. *Pleiones* now flowering should be attended to in potting as soon as they cease flowering. They succeed best in shallow pans near to the glass in the *Cattleya* house. Peat and sphagnum, with a little leaf soil added, is a suitable material. For top-dressing employ peat and sphagnum. They will not thrive in a sour badly drained compost, therefore drain efficiently. *Cattleyas* and *Laelias*, though rooting freely, will require very little water at the roots, and the peat in which they are growing should be such that will permit the water to pass away freely. The sphagnum and the roots growing outside the pots and baskets of such plants as *Aërides*, *Phalænopsis*, *Saccolabiums*, and *Vandas* will require frequent dampings, attention being given to the atmosphere by pouring water on the benches and paths every morning. Very little air will be requisite now, and it must be given below the plants, so as to have its harshness taken off before reaching them. *Cypripediums* and *Cymbidium*s require a good supply of water at the roots. *Odontoglossums* should never be allowed to become dry. They delight in a cool damp atmosphere, and should have a light syringing overhead on fine mornings; but be careful to avoid drip upon the young shoots, not only of these but all *Orchids*. The glass should be kept thoroughly clean, also the woodwork. The temperature of the East Indian house must be kept at 65° by day and 60° at night, or a little lower; Mexican house, 60° by day and 50° by night; the cool house being kept at 50° by day and 40° to 45° at night, allowing in each case a few degrees advance from sun heat.

TRADE CATALOGUES RECEIVED.

The Lawson Seed & Nursery Company (Limited), Edinburgh and London.—*Catalogue of Trees and Shrubs*.

Maekenzie & Moneur, Upper Grove Place, Edinburgh and Glasgow.—*Illustrated Catalogue of Horticultural Buildings and Heating Apparatus*.

H. & F. Sharpe, Wisbech.—*List of Seed Potatoes*.

* * All correspondence should be directed either to "The Editors" or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondence.—Several valuable communications which have been obligingly sent us for all the departments of this Journal cannot be inserted this week, and replies to various correspondents whose letters arrived on the eve of our going to press will appear in our next issue.

"Growing Roses Out of Doors" (*Amateur*).—The book to which you refer as bearing the above title was written by the Rev. O. Fisher, and is published by Messrs. Bradbury, Agnew & Co., Bouverie Street, London.

Insects on Pelargoniums (*W. Begbie*).—We can discover no traces of any insect except aphides on the leaves you sent, and even those are dead, the "white flies" you mention appearing to be simply the dried remains of the aphides.

Dark Climbing Rose for Greenhouse (*L. W.*).—Duchess of Edinburgh (Veitch), crimson, is the darkest in colour of Tea Roses, but it is not a climber. Cheshunt Hybrid has beautiful finely shaped flowers, though not deeper in colour than cherry carmine. The plant is of vigorous growth, and would form a fitting companion for *Maréchal Niel*. Those with *Innocente Pirola* are the three best for training to the roof in greenhouses.

Address (Constant Reader).—The address you require is M. E. Verdier, Rue Clisson, Paris.

Fungi and the Potato Disease (C. D.).—As so much has appeared in our columns lately relative to this subject it is not necessary to publish your letter, especially as it pertains to a phase of the question that has already been discussed.

Seed from Vegetable Marrow (W. W.).—Let the fruit hang in the warm room until the rind is quite yellow, then cut it open and separate the seeds from the pulp by washing them as frequently as necessary; those that sink to the bottom of the vessel will be sound, those that float unfertile. When they are quite dry store them in a paper bag.

Coccol-nut Fibre for Calanthes (Rus.).—Useful as this material is for propagating purposes, it would not be quite suitable for growing your Calanthes in, as they need a more substantial soil. A compost of fibrous loam, leaf soil, a small portion of dried cow manure, with sand and charcoal to render the whole porous, is what you require to obtain these useful Orchids in good condition.

Bees in Conservatory (Bertie).—The structure is not large enough for a hive of bees if it is a moderately strong one. The bees would render the structure unpleasant to timid visitors and would shorten the duration of the flowers, and we doubt also if the bees would be greatly benefited by being placed in the house; some of them would be certain to escape through the ventilators, and would not easily find their way to the hive again.

Heating with Sanitary Pipes (W. W., Otley).—If you send 3½d. in stamps to the publisher and ask him to send you No. 985 of the Journal, you will find a system detailed by which some vineries at Sedbury Park are successfully heated by this method. Mr. Jowsey, the gardener, has secured many prizes with splendid Grapes from the structures referred to. A brick flue of at least 6 feet in length should connect the pipes with the fire. Mr. Matthews of Weston-super-Mare, who is an excellent authority on the subject, has stated in our columns that "unglazed sanitary pipes made of fire clay are better than glazed pipes for forming flues, as they produce a better heat and are not so liable to crack as are glazed pipes." Mr. Peach, who has had much experience with this subject, also states that glazed pipes or socketed pipes should not be employed for heating.

Gas Lime for Garden (D. H.).—It is injurious to all crops, and ought only to be applied to the ground when it is being dug in the autumn, so that several weeks elapse before the crops are sown and planted. It is inimical to grub life generally, and if fresh from the kiln a large handful to a square yard will be a sufficient dressing yearly. Employed in the manner indicated it is safe; but it is not safe as a top-dressing applied when the crops are growing, nor for mixing with the soil immediately before planting. Soot and salt would be good for your garden; and continue your practice of using all the burnt refuse you can obtain, spreading it in the drills in which you sow the seeds, and in the trenches when you plant Potatoes.

Destroying American Blight (L. J. K.).—If you dissolve 6 ozs. of soft soap in a gallon of water, adding a wineglassful of paraffin, and apply the mixture to the trees with a brush, rubbing well into the crevices of the bark, it will destroy the insects. Any portions of the trees that are seriously affected may be dressed with pure paraffin, but it must not be applied to the buds nor to the smooth bark, nor so freely as to drain from the trees into the soil. The soft soap and paraffin must be thoroughly mixed together, and the remedy will be safe and effectual. After your Roses are pruned dress them with a mixture of lime and sulphur with a little clay added to make the "paint" adhere to the stems. In the summer syringe them frequently with a solution of soft soap, and it will to a very great extent prevent the mildew appearing.

Soil for Orchids (Ignoramus).—The Orchids you mention are no doubt potted in a proper manner if you have received them from a nurseryman. They all require very good drainage in the pots, which should be filled about two-thirds of their depth, and a compost of sphagnum, peat, and finely broken potsherds, but the Cypripedium succeeds better if a small proportion of light turfy loam be incorporated with the soil. The Oncidium we do not know; have you not mis-spelt the name? Probably it is either O. pelicanum or O. phymatophilum. The other plants would all succeed in a compost of one-third turfy loam, a similar quantity of peat and leaf soil, sufficient sand and small pieces of charcoal or broken potsherds to keep the soil open, and in the case of the first-named plant, a small proportion of well-decayed manure may be added.

The Hand-Flower Tree (Inquirer, Surrey).—From your description we presume you refer to the Hand Plant of Mexico, *Chlorostemon platanoides*. It is remarkable for the peculiarity of the flowers, which have no petals, and are furnished with a large angular calyx resembling a leathern cup, in the centre of which rises up a column formed of the united filaments, bearing five narrow anthers, which are curved at the top, and with incurved style in the centre, the whole having the appearance of a hand. The tree attains the height of 30 feet, and the first specimen discovered was found near Tolco, in Mexico, where it was held in great veneration by the natives. Forests of it have since been found near Guatemala, whence it is supposed to have been originally obtained.

Digging amongst Fruit Trees (J. S.).—It is not unusual for trees to grow freely when the ground is dug regularly and manured for under crops, and old trees also bear well under such treatment, as may be seen in some of the market gardens near London; but we certainly do not advise you to continue the practice of digging "quite up to the stems as if no trees were on the ground." Further, as your first object is to have satisfactory trees, we should not dig amongst them at all if your ground is light and rich as it appears to be, and they will soon produce wood less luxuriant than before and essentially of a fruitful character. You may spread the soot on the land as you propose, and a liberal dressing of lime would be very beneficial. Keep the ground free from weeds by frequent hoeings during the spring and summer months.

Fruit Shrivelling (Amateur).—The room is too warm and dry. No fire is necessary except for excluding frost, and even this can be kept from injuring the fruit by thick coverings of dry clean straw except during a blast of great intensity and long duration, and even then a little fire heat with much covering is preferable to much fire and no covering. Fruit cannot be kept too cool provided it is safe from frost, and a dark room is preferable to a light one. Fruit, however, such as dessert Pears and Apples, do not ripen so well in a low as in a genial temperature; and if a few at a time are placed periodically in a warm structure, not only will the flavour be more fully developed, but each variety may be had in use over a very much longer period than if left in the fruit room to ripen naturally.

Heating Greenhouse (F. M. S.).—There is no necessity to have more heating power than will exclude frost in the severest weather, a temperature of

40° to 45° artificially being quite sufficient for greenhouse plants. We should prefer having the pipes on both sides of the house about a foot from the sides beneath the staging; but as you object to this on account of crossing the end, where we presume there is a door, you may have the hot-water pipes on one side only, keeping them 15 to 18 inches beneath the stage, at which distance the plants will not be injuriously affected. Two 4-inch pipes will be sufficient—i.e., a flow and return, and they should be fixed "side by side" in preference to "one over the other." The flow rising to the end of the house, and the other declining from that point to the boiler, will afford the needful flow and return—i.e., circulation of the water. We should, as before stated, prefer taking the pipes round the house, say a flow to the doorway, and then dipping so as to cross to the other side, and continuing it as a return to the boiler, which may necessitate sinking a stokehole to have the return socket of the boiler at a proper level to receive the return pipe.

Protecting Dwarf Roses (Goosequill).—As your Roses are so liable to be killed by severe frost we should not hesitate to mulch above the lower buds, and should have no fear of the plants "damping-off." Dried fern is excellent for packing round the stems; failing this use short straw, littery stable manure, or tree leaves, covering the soil thickly with shorter and richer manure. We do not think your plants are killed. Protect them as you propose, and they will probably grow in the spring. If the frost proves very severe and of long duration, fresh covering must be added from time to time as needed. When Roses are planted a safe rule is to cover the roots the same depth as they were before removed from the nursery, and mulch the surface with manure. The buds on Manetti stock should, as a rule, be just level with the soil; if the plants are a year old, as they usually are when removed, the budded portion should be just below the surface, no portion of the stock being visible. We are not sure, however, that we quite comprehend your question—"How deep to plant dormant buds when transplanting them?" but we will readily give you further information if this reply does not meet your case.

Asparagus Dying (J. Bilton).—We are not at all surprised that the roots which you purchased and planted "immediately after the frost last year died," especially as you had them in "a cellar for a month," waiting for a favourable opportunity for planting. In all probability the majority of them would have failed to grow even if they had been planted as soon as you received them. Asparagus should never be planted during the winter months when the ground is cold and wet. The spring is the proper time for planting, just as growth commences. If the soil is in good condition during the last days of March or the beginning of April and growths are produced an inch long, almost every root will grow if carefully taken up and planted. The soil should be free and well pulverised, and trenches should be formed wide enough to admit the full spread of the roots; these should be placed so that the growing crowns are about 2 inches from the surface, leaf soil or other light compost being worked well amongst the roots and a good watering given with tepid water. If the work is carefully yet expeditiously done, without any drying of the roots or breaking off the growths, success is almost certain to follow. We prefer planting when the growths are long enough for the tips to just protrude through the surface, then, with subsequent mulchings, we do not lose one plant out of a hundred. Prepare the beds now, and plant in the spring, taking special care that the roots are not even slightly dried during removal and transit.

Repotting Vines (J. P.).—If the Vines are strong and in moderate-sized pots filled with healthy roots a shift into larger pots is desirable. The time for repotting is in the spring when the young growths are about an inch long, and the work must be done with great care, as the growths are easily broken off. When repotting you must be careful to note that the soil in the centre of the ball of roots is sufficiently moist, and the soil to be used—turfy loam with a third of decayed manure and a sprinkling of bone dust—must also be moderately moist, but not wet. Remove the crocks from the base of the soil, but do not disturb the roots, and pot firmly, leaving sufficient space for a little after top-dressing, and for holding sufficient water to penetrate the mass of soil. If the Vines are in very large pots removing a portion of the surface soil and adding fresh rich compost would probably be sufficient, with otherwise good culture, for insuring a good crop of Grapes. When Vines are repotted in the manner indicated care and good judgment are requisite in watering. We saw last year the advantage of repotting Vines in an experiment that had been made to test the point; but the Vines were in charge of an excellent gardener—Mr. Bardney; with one less competent the results might not have been similar. If you repot the Vines and they do not answer your expectations you must not conclude that the system is wrong, but that you have erred in your mode of carrying it out.

Chrysanthemums in the Open Air (J. B.).—If you plant Chrysanthemums in early spring just when fresh growth commences in the rich deep soil of a sheltered border they will grow and flower well, but whether they will produce exhibition blooms depends on the season, the varieties grown, and your skill as a cultivator. The plan most likely to be successful would be to insert cuttings or slightly rooted suckers now singly in small pots, and plunge them in ashes or coccol-nut fibre refuse in a cold frame for the winter. With good management you would have sturdy well-rooted plants in spring. Then if you dig a trench a foot wide and 18 inches deep at the foot of a wall or fence, fill the trench with rather strong loam with a third of its bulk of manure mixed with it, plant a foot apart, train the plants with single stems and secure them to the wall, water them sufficiently during the summer and mulch over the roots in hot weather, thin out the buds as soon as they are visible, protect the expanding blooms from wet and frost, and prevent injury by earwigs at all times, you may perhaps produce blooms of exhibition quality. We have seen very handsome blooms produced by this mode of culture; but success depends entirely on the skill and attention of the cultivator. Cuttings struck in gentle heat in March or April and duly prepared for planting-out in May answer equally well. But possibly you have not a heated frame in spring, hence our advice to insert rooted suckers as soon as you can obtain them in the autumn. Three or four blooms will be sufficient for each plant of the incurved varieties, but the Pompons may produce several flowers; still many of the buds should be removed, three of the earliest on each stem being retained. The plants will not require stopping, as each stem will naturally break into three or four flowering growths towards the end of summer.

Pruning Apple Trees (J. S.).—When Apple trees are very much exposed to strong winds we do not consider it an advantage to have the heads very thin and open; but if the trees are in the form of an orchard, or are in a sheltered position, a thinning-out of the branches would no doubt be advantageous. The work requires to be done with judgment. As a rule no branches should be shortened, but a portion of those that cross each other should be severed close to the main stems from which they spring. A small-toothed saw will be suitable for the work, afterwards smoothly paring the edges of the bark and cut surfaces with a sharp knife. The most healthy and promising branches should be retained, removing those that are in any way faulty. It must be remembered that cutting

branches off fruit trees is usually followed by half a dozen fresh growths near the severed parts, and if these are permitted to extend the trees are soon more crowded than before; hence our advice not to shorten the branches. The growths issuing from the main stems are easily disposed of in the spring by rubbing them off, not cutting them, when they are an inch long in the spring. This is an important corollary of pruning, and is not sufficiently attended to. We have seen some trees spoiled by pruning when afterwards neglected in dis-budding, and, on the contrary, have seen many fruit trees greatly benefited by the judicious use of the saw and knife in winter and the thumb and finger in spring. The present is the time for thinning the trees; and so far as we understand their condition from your lucid letter we think they would be benefited by the treatment suggested, provided, as we before observed, they are not growing thinly in a very exposed position.

New Roses (J. B.).—It is doubtful if any of the Roses you name will be eligible for competition in the class for new Roses of 1878, 1879, and 1880. Charles Baltet, Edouard Dufour, Madame Chevreton, and Mlle. Marie Verdier are varieties of 1877. We do not know the dates of introduction of Mrs. Berners and Prinee de Joinville, and we are not acquainted with the variety "Madame Levette." Perhaps some of our readers can supply the information. No twelve Roses that can be named, only one plant of each being grown, would enable you to stage twelve exhibition blooms on a given day in 1881, and especially since they have to be purchased and planted. We name some good varieties that will be eligible for the class in question, but we must inform you that even if you purchase all of them your chance of winning a prize in the class next year will be extremely remote. If you plant them now in good soil so as to have strong plants during the summer, and also insert buds in Manetti and dwarf Briar stocks, you may succeed by obtaining blooms either from the cutbacks or the maidens in 1882 that would enable you to achieve your object. Twenty-four good new Roses are Dr. Sewell, Duchess of Bedford, Countess of Rosebery, Harrison Weir, Pride of Waltham, Crown Prince, Duke of Teck, Mrs. Jowitt, Penelope Mayo, Dr. Hogg, May Queen, Mr. Laxton, Robert Marnock, John Bright, Gloire de Bourg-la-Reine, Jules Finger, Henriette Petit, May Quennell, Glory of Cheshunt, Mrs. Harry Turner, Marquis of Salisbury, Masterpiece, Dean of Windsor, and Charles Darwin. You had better add to rather than diminish the number if you intend carrying out your project, especially as a few of those named may not be admissible in a class for "New Roses" in 1882.

Names of Fruits (Owen).—1, Like Bringewood Pippin; 2, Red Ingestrie.

Names of Plants (P. R.).—The Rose you have sent is not *Devonensis*, it more resembles the China Rose Mrs. Bosanquet. We do not undertake to name Roses nor varieties of any florists' flowers, only species. (*H. H.*).—1, *Asplenium viviparum*; 2, *Phlebodium aureum*; 3, *Adiantum cuneatum*; 4, *Adiantum trapeziforme*. (*Mr. Owen*).—1, Too withered, flowers also needed; 2, *Sedum aizoides variegatum*; 3, *Selaginella uncinata*. (*J. W.*).—The plant is a *Tydaea*, but as it was only accompanied by one flower, and that much crushed, we are unable to give the name of the variety, nor do we undertake to name varieties of flowers, only species; still we give the names of those that we can readily recognise. (*H. A. H.*).—The fragments of stems you send are insufficient for us to determine the plant to which they belong, but if you forward flowers or a description of the habit of the plant we may be enabled to name it. (*Field*).—The shrub is *Garrya elliptica*. The Fern is *Aspidium aculeatum*.

POULTRY, PIGEON, AND BEE CHRONICLE.

THE CULTIVATION AND GROWTH OF MAIZE.

THE cultivation and growth of this crop has of late years attracted little attention in this country, although in various foreign lands it is as much, or even more, thought of for profitable cultivation than at any former period. In referring to the experiments and facts relating to its growth in England we shall have to go back for a long period, and even then it assumed somewhat the character of amusement and experiment in the hands of amateurs. Whatever may be its merits the ordinary occupiers of land did not believe that it was of much advantage to them. It should, however, be understood by the home farmers that cultivating Maize in this country is very different from that adopted in America, where the climate and other circumstances are so different from those of England. It must also be remembered that in case of its being cultivated in the agricultural districts of this country to any important extent the same varieties of Maize would not ripen in our climate, which in America furnish so large a portion of its produce. Enormous quantities are imported which stand high in the estimation of feeders of stock, whether of cattle, sheep, pigs, or horses, and the quantity usually consumed here is extremely large, and is sold at such a reasonable price as to greatly depreciate the value of nearly all the cereals and pulse crops commonly grown in this kingdom. The attempts to grow Maize, however, in this country refer chiefly to particular

varieties, which ripen very early, and have been found in favourable seasons and hot dry summers to not only ripen the grain, but to yield a good acreable produce.

The first man whom we can learn attempted the growth in England was the celebrated politician William Cobbett, who had two ears of corn brought to England by his son William from a gentleman in the province of Artois in the north of France, who had cultivated it in a small way for many years. This was in 1826, and induced Mr. Cobbett to import the early variety of corn from New York in 1827, selling the greatest part of it and planting the remainder, and he continued to grow it for ten years in Hampshire. After having recommended its growth to the public he sold considerable quantities every year, and found that the more frequently he grew it from his own saved seed the earlier it ripened. In offering it for sale in this country it was called "Cobbett's corn," and we were induced to plant some on our farm in the year 1828, and occasionally since that time, considering that if it answered for growth to produce corn at all it must be upon the system of interculture, somewhat in the same way that we grew Beans and Mangolds—in alternate lines; we therefore in the first instance planted three sorts of crops in alternate rows to prevent loss and disappointment in the event of the Maize failing. These crops were grown upon the stretch at 2 feet apart upon a capital piece of land, good loam on brick earth. The result was an enormous produce as a whole, one portion being Mangolds, which had just about that time began to attract notice amongst agriculturists, and another portion Potatoes, which proved a good crop; but the Maize did not ripen. It, however, always proved very good provender when passed through the chaff-cutter—stalks, leaves, and green cobs all together. We believe that our Maize did not ripen because the land was too good and loamy, for in all those cases which have come to our knowledge of the corn ripening well and early it was grown upon light, dry, and warm soils. For some years after the continuation of our experiments we saw but little of Cobbett's corn, except statements published in his weekly "Register" of the period up to the time of his death, which occurred in 1835.

In 1849 the question of growing Maize was again taken up by a Mr. Keene, who introduced a variety to public notice under the title of "Forty-day Maize." This gentleman, in order to give publicity to his ideas and its advantages, read a paper at a local farmers' club in the south of England on the 22nd of October in that year on the cultivation of Keene's "Forty-day Maize," and said, "I now lay before the Club numerous specimens of Indian corn and Forty-day Maize in cobs, plants, and shelled-out samples grown in America, in Barbadoes, the south of France, Middlesex, Hampshire, and other places. The Forty-day Maize which had been cultivated by two gentlemen in conjunction with myself near to Southampton was decidedly the best of the whole lot, whether as regarded the thickness of the cobs or the size and quality of the corn, and these samples, as well as those from St. James's Park, London, are thoroughly ripened, and the cobs are regularly garnished with grain from base to apex. It appears that this variety of Maize is cultivated chiefly in the Basque provinces of Spain, where it is looked upon as not far inferior as a diet for the poor to a crop of Potatoes, and they have a name for it bearing no analogy to any other European or American appellation, for in their tongue they called it *Arthoa*. In Spain there are many varieties of Maize—about 130, and the qualities are nearly as various as the varieties, so that they are applied to various purposes—one being retained for human food, another for cattle, a third for poultry, and so on. It is generally sown from the 15th of April to the 10th of June in Spain; but the best time in England is from the 10th to the 25th of May. That is, in fact, the time for sowing in the Pyrenees, the climate there being much like that of the south of England, and the seed ought not to be put into the ground before that time in consequence of late night frosts." Mr. Keene further stated the seed he had brought with him to England was not of the variety usually grown in the Pyrenees, for it had been his study to produce a variety of Maize by hybridisation and otherwise in order to obtain early ripening, which is so desirable in an inferior climate. It is, however, found that the Forty-day Maize bore the often severe frosts of our springs better than any other variety with which he was acquainted, for it had been grown that year (1849) with success under considerable difficulties at Putney in Middlesex; in St. James's Park, London; and on two estates in South Hampshire. The cobs which he exhibited were produced in the latter district in a field of corn as fine as any he had ever seen in the province from which he brought the seed. These samples, compared with those produced in the Pyrenees last year, were superior to the cobs, which were there considered as excellent samples.

As we have taken up the subject in the interest of the home

farmer we must call his attention to a few leading points, not only in the cultivation but the uses and value of the produce. The first point is the soil, for it is upon sharp sand or gravel soils only that we can obtain a crop of ripe corn even in our best and driest summers; and in such seasons where either pulse or Lent corn would fail on account of drought, yet Maize will produce about 50 bushels per acre on the average if we can obtain an early variety. We have seen this year samples of the ordinary round and yellow variety grown and planted on the 18th of May upon thin gravel soil in South Hants, and about half of the cobs were well filled and the corn quite ripe, but the remainder only partially ripe; the stalks were between 6 and 7 feet high, with gross succulent stems and luxuriant foliage. Now this is not quite satisfactory, for if we cannot ripen the whole crop we had far better turn our attention to the use of the stalks, leaves, and cobs in the green state, to be given to dairy cows, horses, &c., in fact any stock are exceedingly fond of it; and when it is cut into chaff the thick stalks, cobs, &c., are available for all animals of the farm, but especially dairy cows, as it will produce butter almost equal to the best grass feeding. There are two points to be considered if we grow it in alternate lines with root crops. The crop should ripen early, but with planting for a fodder crop only; it should be used commencing at about fifty days' growth, for we cannot hope to obtain the forty-day Maize, the meaning of this denomination being that it comes into feather or flower at the end of forty days. This is a very quick growth, for as a fodder plant we know nothing to yield a heavy crop of similar value in so short a time and upon so poor a soil as the round yellow variety, obtainable at any of the seedsmen. It is also a good fallow crop. The seed is usually dibbled or drilled on the flat at 18 inches apart and then horse and hand-hoed once. If planted in the middle of May it would come off as a fodder crop during July in time for sowing Turnips after it, the land being also clean and mellow for any crop which may succeed the Maize. Peruvian guano, or nitrate of soda and superphosphate mixed with ashes and applied by the drill, would be the best manure, at a cost of about 21s. per acre. Two bushels of seed per acre is sufficient. If we could be certain of obtaining the true forty-day Maize we may be sure of a valuable produce in alternate husbandry, because if the lines of Mangolds, Potatoes, or Cabbage were planted 4 feet apart and the Maize at the same distance in alternate lines, the Maize may be left for seed or pulled for green fodder in a cold unfavourable season like 1879. Mr. Keene's professed object in introducing the forty-day Maize was to supply the deficiency caused by the loss of the Potato crop in 1877 and 1878, stating that the green cobs when properly cooked would furnish a vegetable well calculated to take the place of the Potatoes; therefore, by growing both crops in alternate rows we may expect a full and valuable crop, as more room in growth is given for the late sorts of Potatoes, besides the probable protection against blight in the Potatoes furnished by the Maize stalks and foliage. The earliest variety of Maize may probably be obtained of Vilmorin & Co., seedsmen, of Paris.

WORK ON THE HOME FARM.

Horse Labour.—Great impediments have again occurred to the sowing of Wheat, for although most has been done on the dry soils, yet upon the flat-lying cold land there is a considerable portion not sown. On dry soils the land was in a good state from the 1st to the 13th of last month, and the sowing went on without hindrance. The heavy land, however, was not in condition until the 8th ult., giving therefore but five working days in which the sowing could be done. On the 14th ult. and since, up to the time we are writing, frost or heavy storms have prevailed. As the period is now fast approaching when it will be too late to sow Wheat upon heavy land we fear that in some districts large breadths will remain unsown until after Christmas, and will then probably be held over for cropping with Lent corn, so that now we have the prospect of another adverse season for what is termed Wheat soils. It is now of great consequence to decide what is best to be done upon very large tracts of land on which autumn fallowing had been commenced, but could not be completed owing to the flooding rains which have prevailed. We notice on many farms that the grass and weeds have been brought to the surface by steam culture and otherwise. We cannot advise the home farmer to plough this in by deep fallow ploughing, and unless a great change of weather should occur to enable the lumps of grass to be forked together and carted away the best way will be to plough the land very shallow with a double rafter or back stitch furrow, or otherwise a single rafter furrow, so that the grass may still be retained on the top, to be dealt with on the occurrence of the first dry weather in the spring. The land can then be made cleaner, whether intended for Barley or early roots, than in any other way; for in case the land is worked only with the scarifier or lifting drag it will be all the better, whether the spring should prove dry or rainy.

Hand Labour.—Upon all strong or hilly land subject to the wash of heavy rains since the Wheat has been sown men should occasionally look to the water furrows, and clear them of any sand and earthy

sediments, so that the flood water may be kept in its proper channel. Irrigated meadows must now be attended to by the drowner, as the man is called in charge of water meadows, so that all the flood trenches and drawing drains may work freely, for at this time of year the rains bring down from the hills alluvial deposits of great value to the water meadows. Some of these meadows which are not irrigated often receive advantage from flooding after the waters subside; but in order to receive the full benefit of flood water, trenches should always be kept open, so that the water may pass off quickly. In meadows where the grass is coarse and Rushes prevail, these should at this time be cut over with the scythe and removed, in order that the grass in the spring may make an early growth. If it is preferred to make the cattle, such as young stock or dairy cows, eat down the rough grass they will do better, and eat it with more relish to themselves, after an application of a full dressing of manure salt, fishery salt or kainit. Another dressing of the same kind in the month of March and again after the hay crop is removed will be likely to destroy the egg or entozoa of the fluke, for we know that grass growing on the salt marshes is the great antidote for the rot in cattle and sheep. We also caution the home farmer against allowing sheep to feed in the brookside meadows after the subsidence of the flood water, because we have seen cases of sand rot which have killed the sheep, and on a post-mortem examination the livers have been found of a light brown colour and very hard. For nearly all kinds of stock the crop of Champion Drumhead Cabbages will be valuable up to Christmas, and being very abundant this year cattle may receive them on the pastures where the soil is dry. Sheep, also, especially the in-lamb ewes, may have them on the pastures. This is better than folding off the crop on the land, because the quantity can be better regulated and the grass also be eaten at the same time—a matter of great importance to breeding ewes, and is far preferable to giving them Turnips or Rape in the folds. There is this year a very short number of the horned Dorset and Somerset ewes bought for early lambing in all the home counties and southern districts, in consequence of so many of these flocks having been destroyed by the fluke rot. Most of the flocks which are healthy are now lambing down, and generally the lambs are reported healthy. Some of the earliest of these which fell in October are now strong, and together with the ewes are in full feeding upon early Turnips cut with Gardener's cutter, and fed in troughs with cake and bean meal mixed. The lambs running in advance of the ewes should be fed in troughs with white Carrots or Cabbage passed twice through the cutter, and have cake meal strewn over the roots. Twice cutting gives small pieces like dice, which the young lambs can take up and eat without waste; at the same time they should receive the finest Dutch Clover hay made from the second year's growth, and if it has a pleasant aroma the lambs will begin eating it much earlier than any coarse hay like broad Clover. Saintfoin, too, is good if cut young, otherwise it is too coarse. The fattening cattle in the boxes or stalls will now be kept on winter feeding at full allowances for roots, as well as cake and sweet straw; but we caution the home farmer against feeding them with hay, for if the animals have 4 or 5 lbs. of cake and 2 lbs. of bean meal daily strewn over the cut roots hay is quite unnecessary, and likely to disturb their health. Hay-feeding will show no profit, whereas straw will furnish a clean bill of health and profit likewise, especially if the roots given are ripe and such as Cabbage, early hybrid Turnips, or Carrots, the quantity varying from 40 lbs. to 60 lbs. daily according to age and size of the bullocks. Where straw is plentiful it is best given loose in the rack, and any waste will furnish litter for the boxes or pens; if it is scarce it may be cut into chaff and given in admixture with cut roots, cake, meal, &c.

TO OUR READERS.

WE give to-day a full report of the Birmingham Show, and we take the opportunity of announcing, in compliance with the wishes of many subscribers, that with the new year we intend to devote more attention to our *Poultry Chronicle* without prejudice to our other departments; and we have engaged Mr. A. Comyns, B.A., LL.B., well known in the poultry world, to aid us in this department. The principles upon which we have endeavoured always to conduct the Journal are well known to our readers. While we invite the discussion of matters of interest, and shall give the utmost liberty to writers, we shall rigidly exclude anything of a personal character. We appeal to such of our readers as are interested in the subject to give us their aid in making these columns valuable and entertaining. No effort on our part shall be wanting to make the reports of the really leading shows as ample, accurate, and readable as possible. Of the smaller shows we shall give notes as occasion requires, but we cannot afford space for the full prize lists of every show that is held throughout the year. Many of these are of merely local interest, and we feel that we shall better consult the wishes of our readers and our own advantage by devoting our space to original matter of a general kind. Our valued correspondent "C." we need hardly say, will continue to contribute to our columns. With his help and that of other old friends, and the hosts of new ones who, we trust, will assist us, we have every confidence that the *Poultry and Pigeon Chronicle* will become the leading authority on all

points relating to the subjects dealt with, a guide and help to fanciers, and a medium for good in its special sphere.

BIRMINGHAM POULTRY AND PIGEON SHOW.

THIS the oldest, and perhaps still the first of the leading shows, commenced on Saturday last. The entries numbered 3062, being an increase of 164 over last year. The increase was chiefly in the Bantams, which numbered 105 as against 70 last year; the Ducks, which were 163 as against 137; and the Pigeons, which were 815 as against 702. The old wooden pens are now entirely discarded, and the birds were well arranged in wire pens, with the heavier varieties on the lower tier. The weather was singularly propitious, and light for judging the birds all that could be desired. The names of the owners of the prizewinners and other birds we think worthy of special note are given in brackets in our comments on each class, the residue of the birds noticed by the Judges being enumerated at the foot of our comments on the various classes.

Brahmas.—Dark cocks.—A strong class of twenty-eight. First (Lingwood) fine in size, shape, head, and fairly feathered, without hocks; colour moderate, tail a trifle mean; an easy win. Second (Miss E. Russell) a very square-set, shapely, hocked bird, uneven in comb and a little yellow. Third (Norris) another very solidly made one, heavily hocked, rough in comb, and showing a little white in tail. All three winners had great width and depth. Fourth (Joyce) the Palace cup bird and the winner here last season, now out-classed, being too long in back and poor in saddle; v.h.c. (Ansdell) not worth his card; h.c. (Comyns) neat in shape and good in colour, but not out yet and coarse in comb; v.h.c. (Norris) shapely but grizzled in hackle and white in tail. The other noticed birds were—h.c., E. Pritchard; c., Hargreaves, Kendrick (2), Runciman, Nock. Dark cockerels (forty-five) were a good class, but the winners were not, we thought, up to the Palace form, with the exception of the £5 cup bird (Lingwood), which was the Palace cup-winner. He here took an easy lead. The same owner's h.c. was a large good bird, neat in head but imperfect in comb formation and slipped in wings; but for these defects he should have stood second. The actual second (Lady Gwydyr) was a neat bird, good in colour but small and narrow. We preferred the same exhibitor's h.c., 31, a nicely made bird of good colour and neat head, but hocked. Third (J. F. Hall) a fair all-round bird, but too upstanding and rather coarse in comb. Fourth (Clarke) a neat bird, but we should have passed him over on account of his being yellow in colour and having hocks with no middle toe feather. Fifth (Kendrick) one of the largest, and might have stood higher but for his large comb; h.c. (Comyns) good size and shape, but too much comb and tail; v.h.c. (Percival) the Palace fifth, more cochiny than ever; v.h.c., Davies; h.c., (Hall) wants depth; F. Bennett (2), A. Taylor; c., Fowler, Green, F. Bennett. Dark hens (twenty-six).—First (Percival) was, if we mistake not, the second Palace hen; she is nice in colour and foot feather and even in marking, but has rather a Cochin style of cushion. Second Mr. Norris's well-known hen, having apparently been in the wars since her last appearance; she is all round, perhaps, a better bird than the winner, but is rather long in back to please us exactly. Third (Pearson) a bird very much of the same type as first, not quite so clear in colour and rather longer in tail. Fourth (T. C. Peake) good in size and marking, but too long in back and brown on shoulder; h.c. (Comyns) a large evenly marked hen not quite through her moult; 198 (Lingwood) a model in size and shape, but brown in colour and coarse in head; h.c. (Taylor) a solid shapely hen; v.h.c. (Kendrick) good in size, shape, and feather, but too brown; h.c., T. C. Peake (2), Mrs. Ward, Comyns. Dark pullets (forty-five) not a very grand class considering their numbers. First-and-cup (Norris) the Dairy and Palace winner, looking rather overdone; she wins easily by size and shape. Her colour is now fading a little. Her faults in our eyes are a trifle too high a tail, with a cushion sinking a little before it reaches it, and a little indistinctness of marking on breast; her saddle is also rather heavy in marking. Second (Percival) a moderate bird of the silver-tipped style of pencilling on shoulders and back, good on breast, hocked. Third (Wheaton) good in shape and well pencilled on shoulders and back, but very poor in breast and cushion marking, hocked. Fourth (Lingwood) the second Dairy pullet, now showing more brown on back and top of breast than she did then. Fifth (Green) should have been passed over, though good in marking, for her Cochin cushion; c., (F. Bennett) nice in colour and marking, but too slight and long in back; 244 (h.c., Gwydyr) good in size, shape, and colour, but not quite distinct enough in marking. We should have put her in the list somewhere, and pretty high up too; v.h.c., Kendrick; h.c., Holmes, Comyns, Percival, Lingwood, Mrs. Ward; c., Berry, T. C. Peake (2), Haworth. Light cocks (twenty-five).—First-and-cup (G. H. Wood), very solid, broad in saddle, shapely, and short on leg, hocked; comb rather large though even, stained a little on saddle; well ahead of the second (Percival), the Palace and Hull winner we believe. Third (Hall) a fairly good one, diseased in feet. Fourth (Morgan) good shape but heavily hocked and too yellow; h.c. (While) very good in size and shape, but heavy hocks and a shocking comb; h.c. (Ive) might have stood higher but for foul feather in saddle; h.c., Holmes,

Turner, Mitchell, Brecze; c., Birch, Turner. Cockerels (thirty-nine).—First (G. H. Wood) good indeed in size and shape and fine in head, but rather warm in hackle and heavily hocked. Second (Lucas) very neat and stylish, good in colour, with striped saddle, nicely rounded hocks, but rather slight in build. Third (While) nice in shape and colour, moderate foot feather without hock, but rather coarse in comb and one wing out. Fourth (Brecze) a moderate bird with too much tail and foul in saddle feathers. Fifth (G. H. Wood) a good-coloured young one, very fine in comb and nice in shape, but heavily hocked. 119 (Hall, c.) very nice in profile but narrow; 122 (Norris, h.c.), fine in head; 136, v.h.c. (Onions), not worth his card in our view, as though good in shape he was coarse in comb and faulty in colour; v.h.c., Haines; h.c., Lingwood, While, Thorn; c., Mitchell, J. F. Hall, W. W. Walker. Light Brahma hens (twenty-one).—A good class as to size and shape, the chief failing noticeable being yellowness of colour. The first (Lingwood), a grand hen in all points, was quite free from yellow; her only failings were a cushion too much in the Cochin style, and a few dark feathers showing through it. Second (Onions) another good hen, not quite so white or so clear in hackle marking. Third (Birch) weaker still in colour, not so large, and slightly hocked. Fourth (Ansdell) not ready yet and dirty; v.h.c. and c, Mitchell; h.c., Bloodworth, Lucas, J. F. Hall, Mitchell; c., Causer. Pullets (thirty-nine).—As a class better than the hens and much clearer in colour. First-and-cup (Norris) perfect in shape and carriage, fine head and comb, very clear colour, ample foot feather with moderate hock, not over-large, a little indistinct in hackle marking, and clips in her wings a trifle too much; an easy win both of first and cup. Second (G. H. Wood) another very nice pullet all round, carries her wings a little loosely, shows a few dark feathers on saddle, and is heavily hocked. Third (While) a large shapely pullet, well fluffed out, a good white, a trifle confused in hackle marking, moderate hocks. Fourth (While) another good one as to size and colour, but rather underfeathered. Fifth (Mitchell) good size but not quite clear in colour, very broad in head for a pullet; v.h.c. (Bigg) fails in middle toe feather, as also does v.h.c. (Lingwood) also in shape of cushion; v.h.c. (Norris) also deficient in middle toe; h.c. (Haines, 309), second Dairy, might have stood higher here, perhaps her heavy hocks were against her; 304 (While) grand in size and shape but very dark on back; h.c., Morgan, Lucas (2), M. Hall, Haines, Thorn, While (2), Breeze, Naylor, Onions; c., F. Bennett, Morgan, Tedd.

Dorkings were on the whole not such good classes as those at the Palace. Coloured cocks (nine, with four empty pens).—First-and-cup (Pilkington), the Palace winner again rightly placed. Second (B. Smith) a thick-bodied bird, good in all points except that he is a little round in back; h.c., Countess of Dartmouth; c., Hewson. Cockerels (twenty-eight).—First, the Palace winner again to the fore. He is too white in tail for our taste and rather on the small side. Second (Bell) a good-bodied bird, rather long in leg and seems wry-tailed. He was, we believe, unnoticed at Palace. Third (Pilkington) a good style of bird, rather heavy in comb. We preferred him to second. Fourth (Milward) we did not like; he was poor in colour and small; the same owner's h.c., 373, was in our view a better bird in all points except that he was dark in feet; v.h.c. (Drewry) good in size and colour, but gone in comb; h.c. (Smyth) rather narrow but good in all other points, and short in leg; h.c. (Pilkington) grand in body but bad comb and feet; h.c. Hinde (2), Cathcart, Ruttlidge, Drewry, B. Smith, H. Herdman, C. Darby, Peel, Bell. Coloured hens (nine).—First-and-cup (B. Smith) third at Palace. A fine massive bird, short in leg and rich in colour. Second (Cathcart) very neat but small. Third (Drewry) another good-bodied hen, a little longer in leg than the other two. Pullets (eighteen).—First (While) a good-bodied pullet, rather long in leg and white in ear. Second (King) held the same position at the Palace; she is neat but small. Third (Peel) larger and good shape, but white in ear; h.c. (Smyth), the best in body and colour, but not out in comb yet; 494, another good one from the same yard, too young yet; h.c., Troughton, White, Herdman. Silver Greys, cocks (eight).—First-and-cup (Cranston) a true Dorking, short in the leg and square in frame; an easy win. Second (B. Smith) cup at Palace, a good all-round bird; h.c., Cresswell, Miss Shaw. Cockerels (sixteen).—Mr. Cranston here takes first and second with very neat birds of good size, good in comb and colour, well placed. Third (Roe) a moderate one; v.h.c., 423, another good one of Mr. Cranston's; h.c. Stokes. Silver Grey hens (twelve).—First (B. Smith) square in body, low on leg, and good colour, but out of condition. Second (Stephens) smaller but good; h.c., Cresswell. Pullets.—First-and-cup (Cranston) a very pretty pullet of nice colour. Second (Cranston) too pale on breast and hackle for our taste. Third (Mrs. Colville) better in colour but too long in leg; h.c., Cresswell. Any other variety cocks (eight).—First (Pilgrim) a white, the Palace second. Second (Mrs. Walker) another white, better in shape than first, but heavy in comb; h.c., Countess of Dartmouth, Miss Fairhurst. Cockerels (seven).—First (Mrs. Hayne) the Palace cup bird, smaller than second, but better in head and feet. Second (Cresswell) fair in body, but long in leg and heavy in comb. Any other variety hens (nine).—First (Cresswell) a shapely white, neat in comb. Second (Countess of Dartmouth) a good Cuckoo; h.c., Morgan, Stratford. Pullets (five).—First (Cresswell) a large well-footed bird, but very coarse in comb. Second (Stratford) neater in head but not well shown.

Cochins.—Buffs.—Cocks (twenty-four) a very good class. First (Tomlinson), second Palace, also took the cup for cock or cockerel. He is a fine massive bird, of medium shade, even in colour, fine in head, good

in feather except on middle toe. Second (Hind) rather darker in shade, and not quite so large; rough in tail. Not the Hull winner. Third (Brown) the third Hull. Fourth (Tomlinson) a bit coarse in comb and white in foot feather, otherwise good; v.h.c. (Gwydyr) not quite even in colour, v.h.c. (Stanton) a nice lemon; h.c., Pye, Johnstone, Brown; c., Bloodworth, Johnstone. Cockerels numbered no less than twenty-nine, and were a very fine class. First (Tomlinson) second at Palace, a large shapely cockerel of medium colour, good in all points, shows one white feather in tail. Second same owner as first, v.h.c. at Palace, a nice lemon, good all round, a beautiful tail. Third (Pye) the Hull winner, looking well. Fourth (Young) a moderately good bird, rather long in tail. Fifth (Darby) the Palace winner, a very nice lemon, now loose in wing; v.h.c. (585, Brown) a moderate lemon; v.h.c. (Pye) fine in size and shape, but heavily hocked; v.h.c. (608, Brown) too much tail; h.c. (Darby) a lemon, low on legs and squarely made, but heavily hocked; v.h.c. (Tuke) a lemon, with a self-coloured tail, but too much of it; v.h.c., Clatworthy, Swindell, Johnstone; h.c., Tomlinson (2), Procter, Cattell, Nickolls, Swindell; c., Brown (2), Rock, Tomlinson, Tuke. Hens (thirty-six).—Of this and the following class the Judge said that they were the best he had ever seen, and we fully endorse this view. First-and-cup (Tomlinson) the Palace winner again. Second (Percival) a very shapely hen, beautifully fluffed out, but a little high in tail and not quite even in colour, middle toe short of feather. Third (Bloodworth) a very nice Cochins shape, good size and feather, colour streaky. Fourth (Bloodworth) a nice lemon, a trifle high in tail again; v.h.c. (762, Brown) first here last year, not moulted out perfectly even, but might, we think, have stood higher; v.h.c. (Procter) another well-known winner in former years, now rather mixed in shades; v.h.c. (Brown, 788) the Hull winner; v.h.c., Pye, Bloodworth, Procter, Nickolls, Johnstone; h.c., Young, Lloyd, Bloodworth, Darby, Nelson; c., Naden. Pullets (fifty-six) must have been tough work for the Judge. First (Swindell) a lovely lemon pullet, very large, grand shape and feather, but hocked. Second another from the same yard, a sister of the winner, and nearly equal in points to her, but a little short of middle toe feather. These two led the class by a lot. Third (Percival) another good one, but not so large or even in colour as the first two. Fourth (Tomlinson) a nice even Buff. Fifth (Bloodworth) a little mixed in colour on shoulders. All the noticed birds were so good that we hardly like to individualise, but 820 (Procter), a very shapely pullet, a little uneven in colour, struck us as best of them; 829 (Clatworthy), unnoticed, a very promising young one, a little dark in hackle; v.h.c., Bloodworth (3), Clatworthy, Booth (2), Wade, Nelson, Ryland, Causser, Brown; h.c., Darby, Bloodworth; c., Brown, Booth, Adams. Partridge cocks (twenty).—A good class. First-and-cup (Sharpe) a shapely bird in profile, but his wings a trifle too much clipped-in; comb rather large, hocked; good colour, but hardly gloss enough. Second (Percival) a fresh one, very rich in colour and solid in make, but straight in back. Third (R. J. Wood) a very large bird, rather grizzled in hackle and heavily hocked, not quite in condition; v.h.c. (Tudman) good size, shape, and colour, but hocked and rough in comb; v.h.c. (Turner) too dark in hackle again; v.h.c., Grant; h.c., Stretch, R. J. Wood; c., Tomlinson. Cockerels (twenty-five).—Not a wonderful class. First (Clatworthy) a very good all-round bird of medium size. Second (Morgan) the Palace winner we believe, carrying rather much tail with too little fluff. Third (Heathcote) a moderate hocked bird, too long in leg. Fourth (Brown) small and leggy; 665 (F. Robertson) a squarely made thick-set bird, wants a little more size, but even so might have been in the list; h.c., Sharpe, R. J. Wood, Tudman, Sowthern, Dougall; c., Lamb. Hens (seventeen).—First-and-cup (R. J. Wood) good in size, fair in shape and pencilling, wants feather on middle toe. Second (Percival) a fair-sized hen of the old sort. Third (C. Brown) a large moderately marked hen, the Hull winner we think; v.h.c., R. J. Woodman, Tudman, Sharpe, Sowthern; h.c., Sharpe, Beckerley, R. J. Wood. Pullets (twenty-six).—A fair class. First (Sharpe) nice marking, but hardly shape or foot feather enough; of second (R. J. Wood) the same may be said. Third (Sowthern) better shape and feather, but not so clear; v.h.c. (R. J. Wood) good size and fair shape and marking; v.h.c., Tomlinson, Sowthern, Lamb; h.c., Brown, Sharpe, R. B. Wood, Percival, Tudman; c., Stretch. Whites.—Cocks (eleven).—First-and-cup (Weeks) a really fine Cochins of good colour; an easy win. Second (Percival) the Palace winner; v.h.c. (Tomlinson) not quite clear in colour; h.c. (Darby) a nice clear white. Cockerels (twelve).—A good class. First (Chase) must have pressed closely on the old bird for the cup. Second (Darby) a well-known winner, looking a little overdone; h.c., Chase (2), Tomlinson (2), Steven, Darby. Hens (twelve).—A very good class. First (Percival) the Palace winner again, a grand hen. Second (Darby) second at Palace, also a good one. One of Mr. Chase's v.h.c.'s a very good shape; v.h.c., Lady Gwydyr, Chase; h.c., Darby, Chase. Pullets (twelve).—First one of Mr. Darby's well-known winners. Second another from the same yard. It was an honour to win both prizes in this class. There were no less than six v.h.c.'s; all good. They were Fowler, Percival, Chase (2), Darby, Wise. Blacks.—These classes seem to be looking up. Cocks (seven).—First (Darby) the Palace second, brilliant in plumage, but not very large, and too much tail. Second (Procter) the Palace cup-winner we think. His great size for a Black should have put him at the top. h.c., Horsfall, Holmes. c., Badger. Cockerels (ten).—First (Badger) good shape and colour, but rough in comb and wattles, and rather upstanding.

Second (Darby) hardly large enough, but good shape and colour; v.h.c., Badger, Fortey; h.c., Toomer. Hens (nine).—Six of these were noticed. First (Cook) very good in size, shape, and feather, and in nice condition. Second (Darby) not so good in cushion or feather; v.h.c., Turner, Badger; h.c., Cook; c., Horsfall. Pullets (ten).—Mr. Storer's beautiful pullet, third at Palace, came properly to the front here. She has much improved in cushion, and is a rare good one. Second (Fortey) another good one, rather large in comb. The three v.h.c.'s (Pritchard, Storer, and Badger) might easily have won in former years; h.c., Lady Gwydyr, Darby.

Langshans.—Cocks (ten).—These birds seem to be getting settled into a type somewhat between Cochins and Dorkings. First (Lloyd) a massive bird of fairly brilliant plumage and a good bit of tail. Second (Buchan) smaller but very brilliant. Third (Gabb) more comb and tail and great gloss. Fourth (Rowland) too long in leg; v.h.c., Thompson, Croad; h.c., Hinde. Cockerels (twenty-two).—First (Orme) very bright and shapely, large tail, long in leg. Second (Bush) a similar type; as also were third (Garnett) and fourth (Bush); v.h.c., Bush (2), Nickolls; h.c., Croad, Knight, Ripon. Hens (eleven).—First (Hinde), full in breast and good colour. Second (Rowland) somewhat long in back, showing great gloss. Third (Gabb) rather a long tail. Fourth (Hinde) rather more the Cochins type; h.c., Buchan. Pullets (twenty-three).—First and Langshan cup (Nickolls) good shape and bright green reflections. Second (J. Bennett) long in body again, good in colour. Third (Buchan) a Cochins without foot feather. Fourth (Housman) a well-developed Cochins cushion; v.h.c., Thompson, Croad; h.c., Croad, Cook, Tait.

Malays.—Cocks (ten).—First (Fairlie) good outline, but very bare on thighs. Second (Lecher) in brilliant condition; h.c., Copp. Cockerels (twelve).—First-and-cup (Richards) not upstanding enough for our taste; we preferred second (Strugnell), a powerful-looking bird in fine condition; h.c., Brooke (two), Fairlie, Bailey, G. Burnell, Fletcher. Malay hens (fifteen).—First (G. Burnell) rather too level in body and high in tail. Second (Bailey) had the same fault. We preferred h.c. (Lowe) to either of them. Pullets (eleven).—First-and-cup (Fairlie) pretty good in stand. Second (Richards) moderate; h.c., G. Burnell and Brooke.

Crèves.—Cocks (nine).—A good class. First-and-cup (Jackson) good in shape and colour, fair in crest, moderate in muffling. Second (Park) not so good in crest, but better in muffling, good body; v.h.c., Jackson; h.c., Clementson and Chadwick. Cockerels (seven).—First (Jackson) good in all other points, but squirrel-tailed. Second (Williams) much smaller; h.c., Calvert; c., Ward. Hens (six).—First (Lloyd) and second (Jackson) large shapely birds, both showing white in crest; v.h.c., Chadwick; h.c., Park; and c., Wilkins. Pullets (six).—First (Calvert) and second (Lloyd) both nice pullets. We rather preferred the latter; h.c. and c., Ward.

Houdans.—Cocks (twelve).—First (Wingfield-Stratford) good in size, but rather upstanding. Second (Howard) rather deeper in chest, a very white crest; v.h.c., Lane; h.c., Nisbett, Thomas, Lee, Penson. Cockerels (twenty-five).—First (Copplestone) heavy in comb, but good in body. Second (Nickolls) too upstanding again. Third (Thomas) a good-sized bird. The class struck us as being rather undersized; v.h.c., Jackson; h.c., Ward, Wingfield-Stratford, Beedham, Wood, Naylor, Copplestone. Houdan Hens (fifteen).—A very good class. First-and-cup (Wingfield-Stratford) a massive bird, with a grand crest. Second (Sumner) a little long in leg; v.h.c., Howard; h.c., Pilgrim, Lec, Copplestone, Nickolls, Jones, Penson. Pullets (eleven).—First (Wingfield-Stratford) a very shapely pullet, nice in colour, good in crest and muffling. Second (Thomas) rather white in crest, but otherwise good. Third, Lane. We thought the pullets better as a lot than the cockerels; h.c., Naylor, Nickolls, Thomas; c., Pilgrim.

Spanish.—Cocks (four).—First-and-cup (Boulton), rather heavy round the eyes, rough in face; a nice comb. Second (Bull) a moderate face and ugly comb; v.h.c., Le Sueur. Cockerels (thirteen).—First (Lady Allsop) nice quality of face and lobe, but the latter small and folded. Second (Walker) a longer lobe, but rough. We preferred one v.h.c. (Boulton), and one of the h.c.'s (Walker) to second, and are not sure that we should not have placed this latter bird at the top. He had a nice quality of face and smooth lobe, but was dark in feet; v.h.c., Chatterton. Hens (six).—First-and-cup (Chatterton), a grand hen not quite well of her moult yet. Second (Sillitoe), poor in quality of face; v.h.c., Allsop; h.c., Dixon. Pullets (nine).—The first (Bull) had a beautiful lobe, but was rather narrow over eye, as also was second (Walker), for which reason we preferred Mr. Aldridge's h.c. to either of them. She is a bird of very high quality indeed, though a little blue in face; v.h.c., Dixon; h.c., Kirk and Le Sueur.

Andalusians were not strong classes. Cocks, any age (ten).—First (Stevens) too heavy in pencilling and rough in comb. Second (Wilson) better in pencilling, but nothing out of the common; h.c., Troughton; c., Arnold. Hens (fourteen).—First (Arnold) we could not persuade to look at us, but she seemed nicely marked of the dark shade and good in lobe. Second (Ashwell) another very dark one; h.c., Stevens, Wilson, Arnold; c., Jones, Boissier, Bacon, Stevens.

Leghorns.—Brown, any age, cock and hen (six).—First (Gibbs). Both birds nice in colour, brilliant in plumage, and nice shape; cock, rather stained in lobe. Second (Hurst), the cock rather too heavy in comb, striped in hackle and red on lobe. Hen nice in lobe but

poor in colour; h.c., Fraser; c., Arden, Wilson. Whites.—Cock and hen, any age (six).—First (Bradbury). The cock smart but small, and pink in lobe, with a neat comb; the hen very dirty. Second (Caldicott), cock too high in tail and stained in lobe; hen too heavy in comb; h.c., Morecraft. In this class Mr. Fowler showed a pair of Cuckoo Leghorns, a recent importation. They were nice in marking, fair in shape, and defective in lobe. They could not be noticed by the Judge, as they were only sent at the last moment to the White class.

Minorcas (six).—A moderate class rightly judged. First, Roscorla. Second, Wilson; h.c., Harwood.

Sultans were a fair class of seven. First, Beldon. Second, Eyles. Third, Rawnsley, were even in quality; h.c., Muir. The first-prize hen died during the Show.

Hamburghs.—Black cocks (eight).—First (Heath) best in lobe and colour, but rather rough in comb. Second (Bracewell) a neat bird, with a comb too much up at back, otherwise fine; h.c., Hinde, Mallinson. Cockerels (eighteen).—First-and-cup (Kellway) good in lobe, nice style and condition; passed over at Palace, we believe. Second (Rawnsley) very stylish and in brilliant condition. Third (Bell) a shapely bird of even quality all round. 1667, v.h.c. (Serjeantson) very nice in lobe; v.h.c., Hogg, Serjeantson; h.c., Kilvert, Booth, Lawson. Hens (eight).—First (Gladstone) very neat in head, clear in lobe, and bright in feather, but slightly ticked with white on neck. Second (Heath) a shapely bird, in nice condition, but not clear in lobe; h.c., Copeman, Caldicott, Wilde. Pullets (nineteen).—First-and-cup (Copeman) a very stylish pullet, good in colour, comb, and lobe. Second (Booth) good in other points, but crooked in comb. Third (Kellway) rather pale in head, and not in condition; v.h.c., Garnett, Hogg, Kilvert, Heathcote, Serjeantson; h.c., Serjeantson, Bell, Kilvert, Fellowes. Golden-pencilled cocks, any age (fourteen).—First-and-cup (Beldon) the Palace and Hull winner, best in style, very rich in colour, splendid in tail, fair in comb, good in lobe. Second (Fielding) very neat in head and comb, but not up to the winner in tail or condition. Third (Burn) another rich-coloured one, better in tail than second, but behind first in this point; v.h.c., Whittaker (2). Hens, any age (eight).—First-and-cup (Driver) the first at Palace, very neat, nicely marked, and in fine bloom; an easy win. Second (Bell) rather twisted in hackle and not in show form. Third (Fielding) a neat pullet, but not up to the other two in tail marking. Silver-pencilled cocks, any age (six).—First (Rawnsley) a very neat bird, but rather overdone. Second (Beldon) not equal in tail marking to the winner, otherwise a good one; h.c., Fielding, Pickles. Hens, any age (six).—First (Fielding) neat in style, good in marking, but uneven in comb. Second (Beldon) meaty in comb again, though better in this than first; behind her, however, in marking; h.c., Rawnsley, Pickles. Golden-spangled cocks, any age (thirteen).—First-and-cup (Caleb May) a very stylish bird, good in marking and lobe, fair in comb, in splendid condition. Second (Thomas May) rather heavy in comb and wild in the pen, marking moderate. Third (Fielding) a large-bodied bird in brilliant condition; v.h.c., C. May; h.c., Parsons, Jackson, Dent, Westley, Bracewell. Hens, any age (nine).—First (Duckworth) neat in shape and head, very rich in colour, and good in markings. Second (Randall) looked ill about the head and overdone; she was nice in shape and colour, with moderate marking. Third (Blakeman) had also a pallid head, and was loose in tail; h.c., Dent, Simpson, Driver. Silver-spangled cocks, any age (ten).—First (Rawnsley) good in size, moderate in comb, nicely marked. Second (Beldon) very stylish and well marked, but a bit heavy in comb, in better condition than the winner; these were both fresh birds. Third (Ashwell) the Palace third, a nice bird, but rather heavy in comb, light in saddle hackle; h.c., Randall, Campbell. Hens, any age (eleven).—First-and-cup (Beldon) the Palace and Hull winner, a beautifully marked hen, rich in colour, and neat in head. Second (Ashton & Booth) another nicely marked one, but a good deal behind the first. Third (Fielding) well marked again, but out of sorts and loose in tail; v.h.c., Pickles; h.c., Rawnsley, Randall, and Campbell.

Game.—Black-breasted Red Cocks (eighteen).—First (Lyon) an easy win. The cup here last year as a chicken; good in colour, rather short in head, and perhaps flat in shin. Second (Halsall) a good hard bird, but apparently suffering from a corn; not sound in tail. Third (Matthews) a fine bird of the usual Stowmarket style, good colour and quality, but perhaps a shade too light. Fourth (Dutton) a fair bird of good colour; h.c. (Beck) same stamp as third, but rather rusty in fluff. 1354 (Lyon) we think should have been noticed in spite of his back claw having lost a nail; h.c., Walters, Frith; c., Frith. Cockerels (thirty-four).—All four prizes go to Mr. Lyon, who also takes both challenge cups. The cup-winner out of condition, for which some people would have put him below second, a bird of fine quality and good in tail, but faulty in hocks. Third a good hard bird of good style, but dull in colour. Fourth out of sorts again and swelled under the throat. We should have put 1390, v.h.c. (Pope), a good all-round bird, before him. 1367, h.c. (Pope), a very promising cockerel, will make his mark later on. 1380, h.c. (Brierley), dull in colour and beesy on wing. 1381 (Harley), a very smart bird, might have been in the list; perhaps his throat being skinned may account for it. 1387 (Matthews), h.c., wants time. 1389, h.c. (Goodwin), too dark in eye. 1395, h.c. (Beck), a pretty bird. 1397 (Fletcher) might well have stood second had he been in condition. 1399 (Mynors), h.c., bad tail; h.c., Staveley, Brierley. Hens (eighteen).—First (Matthews) a fine reachy hen, very like

the Palace winner, pencilled in wing, for which reason many would have put second (Pope) before her. This was a first-prize winner here last year. Third (Harley) a bird of good quality, but not equal to 1487 (Lyon), unnoticed. 1484, h.c. (Dutton), the second here last year. 1492, v.h.c. (Staveley), a well-known old hen of good quality. 1497 (Caton), h.c., a very bright bird, rather pencilled on wing. v.h.c., Lyon; h.c., Mason and Walters; c., Weeks. Pullets.—A wonderful class of thirty, must have been difficult to judge. First (Lyon) took the £30 challenge cup for pullets, and the cup for best Black Red hen or pullet. She was a bird of wonderful reach and quality, but rather mossy in flights on one side. Second (Harley) the Palace winner. Third (Pope) wants time. Fourth (Harley) we should have put behind some others, notably 1525 (Halsall), h.c., which some fanciers thought worthy of the cup. 1528, h.c. (Lyon), the Oxford winner. 1526 (Pope), h.c., a very good bird but for white earlobes. Most of the other h.c.'s might have easily been first in any other year. They were Mason, Horton, Lyon, Brierley, Walters, Maynard, Halsall, Pope, and Gibbs. Brown Red cocks (fifteen).—First (Matthew) very good style, but not the recognised colour. Second (Brierley) better in colour but not so fine in quality. Third (Martin) very good in colour and condition, but a trifle short in head. Fourth (Ward) fine in head and good in colour; h.c. (Ashburner) too much hackle; h.c. (Mercer) full of quality, and might well have stood much higher up; v.h.c. (Bothway) a very good all-round bird, well shown. Cockerels (twenty-seven) were not a strong class for Birmingham. First and three-guinea cup for best Game cock in Show, also section cup (Mercer), a wonderful bird in colour, but in our opinion behind the old Black Red cock as a Game bird. Second (Matthew) a good reachy bird, dark in face but hardly lemony enough. Third (Dance) a smart bird, but quite enough hackle. Fourth (Bell) rather long in tail and not quality enough; v.h.c., Dunstan; h.c., Ward (2), Richardson, Butler, Bond, and Warner; c., Martin, Dance, Brierley, Ashburner. Hens.—A good class. First (Mercer) a fine hen in all points, and properly placed. Second (Matthew) a very stylish reachy, hen well shown. Third (Heaton) a good powerful hen, nice coloured hackle, rather red in face; h.c., Warner, Woolf (2), Bothway, and Gibbs. Pullets.—First (Mercer) more reachy and better coloured in hackle than second (Brierley) a very neat bird. Third (Dance) another very good pullet, short close hackle. Fourth (Martin) rather too light in hackle; h.c. (Ward) a very smart promising pullet with plenty of style; h.c. (Matthew) a very stylish pullet, rather too red in face; h.c., Warner and Ward. Duckwings.—Cocks (eleven).—First (Harley) a bird of beautiful colour and style. Second (Harley) a good-coloured bird, blind of an eye, heavy in tail and hackle, and ticked in fluff. Third (Matthew) we preferred to second, and should have so placed him. He was beautiful in head and first-rate in hackle and colour, perhaps rather short in leg; h.c. (Staveley) we also preferred to second; he is good in colour, shape, and style, and well might have stood third; h.c., Westcott and Harley. Cockerels.—First (Goodwin) a reachy hard-feathered bird with splendid head and tail; his faults are stripe in hackle and barred wing. Second (Phillips) a very good chicken, striped in hackle, rather young; in a month's time would run winner close. Third (Harley) the Palace winner, not in form; h.c., Goodwin, (2), Frith, and Matthew. Hens (seven).—First (Wharton) a good-shaped bird well tucked up, but lacking in quality. Second (Staveley) a well-shaped stylish hen of very good colour, and we think she might well have stood first. Third (Careless) fair in colour and style, but we thought 1581 (Harley) a better bird in all points. Pullets.—First (Potter) a bird of fair style, well shown, but not in our opinion best in the class. Second (Goodwin) fine in style, good colour in breast, but pencilled in flights. Third (Staveley) a very stylish reachy pullet, hard in feather, and good colour. 1584, c. (Goodwin), a hard-feathered, stylish, good-coloured pullet, good head and eye, and our choice for first; c. (Staveley) another good-coloured stylish pullet, which we also preferred to the first and second. Any other variety Cocks.—First (Hulme) a yellow-legged Pile, a good-coloured bird well shown, but thick in head. Second (Walker) a yellow-legged Pile, which if well shown would have beat first. Third Frith; h.c. Frith. Cockerels.—First (Lyon) a stylish yellow-legged Pile, capital in head and tail, but a little light in hackle. Second (Brierley) a very hard-feathered stylish chicken, capital in colour on hackle, but rather dark on saddle and wing bar, but not up yet. Third (Heaton) the Palace cup-winner, and might have stood higher if in form; his colour on saddle and wing is rather light; h.c. Bothway, Frith, Heaton, Brierley. Hens (six).—The winners all yellow-legged Piles. First (Brierley) a smart bird; second Halsall; third Walker. Pullets (six).—First (Halsall) a yellow-legged Pile, good in head. Second (Brierley) a nice willow-legged Pile. Third (Bell) also willow-legged; c. R. Walker.

Asiels were one more in number than last year, but not quite of such fine quality. As there is no question that the great object of the Indian breeders of these birds was the pit, the Judge (Captain Astley), as we think correctly, judged them with a special reference to fighting qualities. In cocks any age (fourteen) Miss Mortimer was first with a White, very stylish and upstanding, and hard in feather. Second (Sugden) was a good type of bird, bold and erect, but not in condition. Third (Countess of Dartmouth) a dark bird not quite of such style as second. Fourth (Dutton) a handsome Spangle. 1622 (Bunnett) a powerful bird but rather coarse. 1624 (Ricketts) a very good old imported bird. 1626 (Dutton) good in some points, but very short and chubby in beak and head. 1627 (Livett) a Malay evidently.

Hens (fourteen).—First (Miss Mortimer) we did not like for her place; the hen is very muscular but with no style, she looks lumpy and common. Second (Dutton) a smart-looking hen and rightly placed. Third (Ricketts) a black and white Spangle, probably owed her position to her colour. Fourth (Dutton) another very good hen, grand in muscle, but quite crooked in beak. Of the rest we most liked 1629 (Montessor), the correct type of a good strong hen, and 1631 (J. D. Peake) a very good small hen which might well have been in the list.

Polish.—White-crested Black cocks (six).—First (Unsworth) a fine crest, not quite out yet and thus rather loose. Second (Rawnsley) small, and crest rather too much backward in lie; 1260 (Perry) another large crest not quite up; v.h.c., Evans Broad; h.c., Shaw. Cockerels (nine).—First (Fearnley) large and good in crest, except that there was a want of feathers leaning to the front, for which reason we preferred second (Partington), a small bird with a globular crest; v.h.c., Rawnsley; h.c., Shaw (2), Lecher, North, and Battye. Hens (six).—First (Partington) a nice-shaped crest, not over-large. Second (Broad) larger in crest, but showing more black feathers in front; v.h.c., Shaw (2); h.c., Unsworth. Pullets (five).—First (Partington) nice shape and good globular crest. Second (Shaw) larger in crest, but hump-backed; h.c., Rawnsley and Shaw. Golden cocks (eight).—A fine class. First (Huish) nice in spangling and large in crest, but showing a good many white feathers in it, as also did second (Partington), whose crest was rather flat at top; v.h.c., Rawnsley and Fearnley; h.c., Broad and Unsworth. Cockerels (six).—First (Jarvis) a very good bird all round, large crest, good colour, and marking. Second (Millner), not very far behind the winner, but showing more pen feathers in his crest; v.h.c., Dawson. Hens (seven).—First (Partridge) fair in marking and grand in crest, but some white in it. Second (Partington) another nicely marked one, not so large in crest; v.h.c., Shepherd; h.c., Boothby, Hopwood. Pullets (nine).—First (Jarvis) and second (Oscroft) very nice birds in crest, colour, and marking; v.h.c., Boothby; h.c., Fearnley, Huish, Adkins. Silvers.—Cocks (seven).—First (Huish) a very large crest, almost entirely white. Second (Allan Smith) good in size, shape, and crest, and fair in marking; v.h.c., Adkins (2); h.c., Huish and Millner. Cockerels (six).—First (Rawnsley) an evenly marked one with a crest neatly tipped with black. Second (A. Smith) not a bad one, but far behind the winner; h.c., Bloodworth and Adkins (2). Hens (seven).—First-and-cup (Adkins) nicely spangled and good in crest. Second (Adkins) not quite so good in marking, but splendid in crest; v.h.c., Bloodworth, Huish, and Smith; h.c., Bloodworth and Adkins. Pullets (seven).—First and second again went to good birds of Mr. Adkins'; v.h.c., Rawnsley, Adkins, Bloodworth, and Smith.

Any other variety, cock and hen (twenty).—First (Lowe) were good La Flèche. Second (Bradbury) were a fine pair of Plymouth Rocks. Third (Gabb) were called Eymore Blacks, whatever they may be. Have we here the origin of the Langshan? They looked just like Langshans without foot feather. Will Mr. Gabb kindly tell us where they come from? v.h.c., Muir (Scotch Greys); h.c., Ridley (La Flèche), Calvert (La Flèche), Crewe (Chamois Polish, 2), Darby (Silkies). There were also in this class Courtes Pattes and some cross-breeds.

Bantams.—Golden or Silver-laced cock and hen (eleven).—First (Serjeantson) Golden, good in all points but tail marking. Second (Serjeantson) Silvers, the cock rather loose in comb, markings good in both birds; h.c., Peel, Serjeantson, Bracewell (2), Stephens; c., Browne. White clean-legged cock and hen (five).—First (Crowther) small, neat, and good in colour. Second (Rawnsley) rather larger and not quite so clear; h.c., Crowther. Black clean-legged, cock and hen (fifteen).—First-and-cup (Clapham) the Palace winners, a very neat pair, nice in colour and condition, very fine in lobe. Second (Phelps) moderate; v.h.c., Rawnsley; h.c., Stephens, Troughton, Davies; c., Crowther. Game.—Black-breasted and other Reds.—Cock, any age (fourteen). A good class. First-and-cup (Addie) a very stylish Black Red, good in colour. Second (Morris) another of similar stamp; v.h.c., Addie, Morris; h.c., Hore; c., Stamps. Hens (eight).—First (Addie) a very smart Black Red, good in style and colour. Second (Fletcher) a good-coloured Brown Red. Game.—Any other variety.—Cocks, any age (seven).—Only a moderate class. First (Fletcher) a stylish Duckwing, not clear enough in wing; the Palace winner. Second (Ward) a fair yellow-legged Pile, not up in feather. Hens (eight).—First (Fletcher) a willow-legged Pile, very stylish but rather large. Second (Ward) a yellow-legged Pile; h.c., Careless, Hodges; c., Thomas. Bantams.—Any other variety.—Cock and hen (eleven).—Only a moderate class. First (Stamps) Duckwing Game Bantams, very moderate in quality. There was clearly an oversight in awarding this prize, as they were in the wrong class; a protest was entered, but the decision of the Judge was upheld, on what ground we fail to see. Second (Law) Rose-combed Cuckoos, too large; h.c. (Cooke) a very nice pair of Black-booted Bantams; h.c. (Fletcher) a nice pair of Speckled-booted.

Ducks.—Aylesbury (eight).—First (Fowler) weighed 18 lbs., and were a good pair. Second (Hedges) were 17 lbs. 8 ozs. Third (Fowler) 16 lbs. 8 ozs.; v.h.c. Fowler, Gunn; h.c., Snell. Rouens (thirty).—The winners here (Unsworth) also took the cup for this and the preceding class; they turned the scale at 19 lbs. 4 ozs., while second (Brierley) were 20 lbs. 10 ozs. Third (Mallinson) were 19 lbs.; and fourth (Wakefield) the heaviest in the class, though not the best in

points, were no less than 20 lbs. 12 ozs.; v.h.c., Partington, Unsworth, Wakefield, Knight; h.c., Kettlewell, Fowler, Mallinson, Rawson, Snell, Gladstone. Pekins (twenty-six) were a fine class. The winners of cup, first, and second came from Messrs. Fowlers' yards, and were the best in points, being large and upstanding; we noticed, however, that the neck feathers were twisted so as to form a crest on the neck, which we did not like. Third (Allen) another good pair; v.h.c., Nickolls; h.c., Crewe, Perry (a fine pair), Knight, Allen, T. C. Peake (2), C. Morgan. Cayuga (six).—First (Webb). Second (Coulson); h.c., Naylor. East Indian (twelve).—First and second (Burn). Third (Maynard); h.c., Browne (2), Hayne, Maynard, Schofield, Earle.

Ornamental Waterfowl.—Mandarins.—First (Perry) very neat and in grand bloom. Second (Wade), perhaps clearer in marking than first; v.h.c., Gladstone; h.c., Boutcher. Carolina Ducks (seven).—First (Perry) in splendid condition. Second (McGlashan); v.h.c., Boutcher; h.c., Yardley, Pratt, Robinson. Call Ducks (eight).—First (Gladstone) of the Wild Duck type. Second (Jagger), Whites; h.c., Hartopp, Crowther. Any other variety (eight).—First-and-cup (Gibbins), Paradise Ducks. Second (Perry) White-faced Whistlers; v.h.c., Serjeantson (Spotted Bills), McGlashan (Bahamas), Yardley (Ruddy Shell Ducks); h.c., Serjeantson (Chili Widgeons).

Geese.—White (five).—First-and-cup (Garforth) scaled 43 lbs. Second (same owner) 42 lbs. 8 ozs.; v.h.c., Rawson (2); h.c., Snell. Grey or Mottled (twenty-six).—A fine class. First (Stott) were 41 lbs. 8 ozs. Second (Rawson) 40 lbs. 1 oz. Third (Hawkins) 39 lbs. 1 oz.; v.h.c., Kettlewell, Colville, Watson, Bradburne, Smith (2), Sutcliffe, Bower; h.c., Countess of Dartmouth, Lawden, Williams, Tyler, Snell, Graham (2), Colville.

Turkeys.—Cocks (twenty).—First-and-cup (Wykes) did not weigh so heavy as second (Gladstone) which was 36 lbs. 8 ozs., or third (Kendrick) 34 lbs. 8 ozs.; v.h.c., Colville (2), Lewis, Bibb, Neville, Nutt, Wykes; h.c., Longman, Ward, Watson, Shenton. Cockerels (twenty-two).—First-and-cup (Wykes) won for points as against size. Second (Kendrick) weighed 26 lbs. Third, Wykes again; h.c., Lady de Rothschild, Kettlewell, Kendrick, Watson (2), Longman, Williams, Lawden, Nutt, Lewis. Hens (twelve).—First-and-cup (Gladstone), Second (Kendrick). Third (Watson); h.c., Wykes (2), Nutt. Pullets (fourteen).—Cup, Wykes. Second, Kendrick. Third, Wykes; h.c., Kendrick (2), Nutt, Watson.

PIGEONS.

The Pigeons at Birmingham occupy as usual the gallery. Weather favours the Show this year, and we have certainly never seen the Pigeons to such advantage before. Their numbers are 815 pens—about one hundred higher than last year; still they are small compared with the Palace, and some of the classes with good prizes are not well filled. Of course the *spécialités* of Birmingham, such as Dragoons, Antwerps, and Tumblers, are in force.

Carriers head the list. The cup Black cock (Montgomery), priced at £1000, is a magnificent bird all round; his size is fine, and the form of his beak wattle perfection. The second (Fulton) is a little behind him in beak wattle, but very good in eye. Third (Maynard) good, but beak wattle fails a little towards the end; h.c., Maynard, Baker, Fulton. The winning Black hens are both remarkable birds. First (Baker) wonderful in beak for a hen. Second (Fulton); h.c., Maynard (2). The first Dun cock (Maynard) is well ahead. The second (Fulton) good, but a little irregular in eye wattle; h.c., Baker, Maynard, Siddons. The first Dun hen (Fulton) is a little out of condition, but still easily first for her form. Second (Fulton) is larger in wattle; h.c., Maynard. For any other colour cock both prizes went to Blues. The first (Hewitt) a grand bird, but we preferred the wattle of the second (Baker); h.c., Maynard, Fulton. The cup young Black (Burton) is splendid in form, and indeed all the winners promising. Second (Maynard). Third (Fulton); h.c., Billyeald, Burton, Fulton.

Pouters, considering the classification and prizes, are not so numerous as we should expect. The first Red cock (Baker) would not show to advantage when we saw him. The second Yellow (Sugden) is fine in globe, but shows too much white on the breast; h.c., Fulton. The first Yellow hen (Fulton) good. The second Red (Sugden) stylish, but rather small; h.c., Sugden, Fulton. The cup Blue cock (Sugden) is a correctly marked bird, with fine globe, but not improved by having a bare patch on his breast. Second (Fulton); h.c., Baker, Fulton. The two winning Blue hens are both slim and elegant. The first (Baker) best in length. Second (Fulton); h.c., Wardle, Sugden. We liked the form of the first White cock (Fulton), though after the Blues he looked small. Second (Baker). In the classes for any other colour all the prizes go to Blacks. Cocks.—First (Baker). Second (Crofts); h.c., Fulton, Sugden. Hens.—First (Crofts). Second (Fulton); h.c., Sugden, Baker.

Tumblers are quite a feature of the Show, and have no less than eleven classes. The first Almond (Braid) is a beautiful rich real Almond in colour. Second (Weston) darker. Third (Fulton) light in flights, otherwise good in colour—all three fine in head; h.c., Baker, Weston, Fulton, Yardley. Any other colour, Short-faced.—First (Braid) a very good Black. Second (Braid) a red Agate. Third (Weston) a yellow Agate; h.c., Bott, Weston (2), Yardley. Blue Beards are first and second (both Weston) in the next class, both pretty little birds; h.c., Martin, Fulton. Reds win both prizes in the Rosewing classes. First John Wilkes, jun.; second Crndging-

ton; h.c., Doughty, J. Brettell Wilkes (2), J. Wilkes, jun., Gamon. First (Crudginton) in Mottles is a good Black. Second (Careless) another very pretty bird, but with a little too much white; h.c., Mapplebeck, Crudginton; c., J. Wilkes, jun. Badges follow, a variety hardly known beyond the Tumbler circle. First (Hadley) and second (Crudginton) are very rich Reds; h.c., Wilkes, Hadley (2); c., Wilkes. Then come Saddles with magpie marking and mottled heads. First (Wilkes) is a Black, second (Crudginton) a Blue; v.h.c., Trebble, Clarke; h.c., Jackson, Wilkes; c., Mapplebeck (2), Doughty, Jackson, Wilkes. Self-coloured Muffed Tumblers are a large class, the winners both Black. First (Woods); the second (Bott) very fine in foot feather; h.c., Bott, Southall, Crudginton; c., Ludlow, Collins. In any other variety Muffed Redbreasts win both prizes. First Woods, second Bott; h.c., Southall, Crudginton; c., Ludlow, Collins. Long-faced Balds or Beards number twenty-six. First (Woods) is a lovely Blue Beard. Second (Mapplebeck) a Black Beard. Third (Woods) a Black Bald, clean cut but dull in colour; c., Clarke, Lund, Bowler. Clean-legged Long-faced Tumblers of any other colour muster twenty-six. First-and-cup (Woods) is a Yellow very correctly mottled. Second (Crane) a Red. Third (Mapplebeck) a Yellow.

Barbs are few. In the old class both the winners are black, and both splendid in head. The first (Montgomery) a little the smallest. Second (Baker); h.c., Baker, Fulton. In the young class a most promising Red is first (Sutton), and a Black second (Sutton). h.c., Baker.

Trumpeters.—The winning Mottles are both marvellous birds in rose and foot-feather; the second (Fulton) much lighter in colour than the other (Hutchinson). There are several other fine birds in the class; h.c., Shaw, Hutchinson, Baker. Two lovely Whites win in the next class, the first (Hutchinson) best in rose, the second (Shaw) in condition; h.c., Hutchinson, Wardle.

Runts require larger pens. First (Stephens) the well-known French Silver. Poor thing! he could hardly move in his pen. Second (Price) another of the same colour; h.c., Stephens, Green.

Archangels.—The cup (Whichello) goes to a nice but not a wonderful bird, too blue in tail. Second (Whichello) has brown marks on the wing, which we observed on one of the Palace winners. We much liked the third (Stevens), a very purple-breasted bird; h.c., Stevens.

Fantails (White).—The cup-winner (Loversidge) is a small bird with flat and very sound tail. Second (Cresswell) good of the same type, he held the same position at the Palace. Third (Stevenson) very small and nervous. Pen 2559 (Serjeantson) a splendidly round tail; h.c., Serjeantson (2), Loversidge, Cresswell (2), Crofts. Any other colour.—First (Cresswell) a Blue with large and very round tail. Second (Stevenson) a Black Saddle, very good in black; h.c., Shaw, Warhurst.

Nuns.—All Blacks. First (Woods) small and good in colour. Second (Dale) good in flight; h.c., Shaw, Crofts.

Swallows.—First-and-cup (Tedd) a Black, better in marking than in colour. Second (Bulley) a rich Red, nice in foot feathers. The class is a good one, but many birds fail in foot feather; h.c., Crofts, Sutton, Wardle.

Magpies have three classes. The cup goes to the first Black (Bulley), a nice small bird with light bill. Second (Stevens) is rather too Tumbler-like; h.c., Bulley, Tedd. The Red winners are all good. First Bulley. Second Tedd; h.c., Tedd, Bulley. Any Other Colour.—A good Yellow of Mr. Tedd's takes first and second; h.c., Bulley. Mr. Tedd shows a bird (2617) of very curious colour, a kind of Silver, each feather laced like an Andalusian fowl.

Jacobins are not such classes as we should have expected at Birmingham. Blacks are only four. First (Weyman & Buchanan) close in hood. Second (Goold) not quite so good in this respect, but brilliant in colour. The cup goes to the first Red (Fulton), very perfect in all points of form, though he might be brighter in colour. Second, Weyman & Buchanan; h.c. and c., Dale. The first Yellow (Weyman & Buchanan) is fine in chain and bright in colour. Second (Dale) a pretty little bird, not very sound in colour; h.c., Fulton; c., Dale. Whites take both prizes in the Any other colour class. First (Waters) rather coarse, but good in chain. Second (Dale) smaller, but with hood too much thrown back; h.c., Weyman and Buchanan (2), Fulton; c., Maynard.

Turbits have now three classes, and share a cup with Owls. First in Reds or Yellows (Fulton) is a splendid little Red, rich in colour and down in face. Second (Crafer) a very fair Yellow, short in beak; h.c., Cresswell; c., Baker. A well-known old Silver (Baker) wins in the next class, rather short of gullet. Second (Fulton) a Blue, a nice bird all round, and short on the leg; v.h.c., Woods, Baker; h.c., Dale; c., Shaw. First in the other class (Cresswell) is a tiny Black, evidently a hen, very fine in head. Second (Fulton) a coarser Black, but with the merit of clean thighs; h.c., Braid.

Owls are not numerous. Two Whites win in the Foreign class, and the cup goes to the first (Woods). Second Baker; h.c., Fulton, Wardle; c., Leake. In English (seven entries) a Powdered Silver, splendid in head, is first (Woods). Another Silver, not his equal second (Waddle); h.c., Fulton and Shaw; c., Shaw.

Dragoons have six classes. We are sorry to see many birds with very heavy beak wattles winning again. The cup Blue cock (Smith) is excellent in colour and fine in style, but in respect of wattle does not please us. The second Blue (Shewell) has also much wattle;

h.c., Osmond (2); c., Beach, Fulton, Smith, Mitchell. In Any other colour cocks first (McCandlish) a Yellow, fine in colour and shape, but as big as a Carrier. Second (Smith) a very stylish Blue Chequer; h.c., Pratt, Morpus; c., Beach, Smith, Shewell. In hens we remarked the beautiful bars of the first Blue (Smith), though her beak is too large for our fancy. We preferred the same owner's second; h.c., Osmond, Fulton; c., Mitchell, Simkins. Any other colour hens.—First McCandlish. Second Smith; h.c., Smith; c., Osmond. The two winning young Blues much pleased us; both are fine in shape and dark in eyelash. First Smith; second Osmond; h.c., Burton, Gaunt; c., Morpus, Osmond. Any other colour young Dragoons.—First McCandlish; second Osmond; h.c., Shackleton, Osmond. c., Yardley, Ludlow, Morpus.

Antwerps.—We have seldom seen such a lot of really "short-faced" birds. Too often Antwerps are of a nondescript type which seems to puzzle judges, and in which we can see little beauty. Hardly an indifferent bird was to be seen in the prize list, and the winners almost defy criticism. The cup Red Chequer seemed well to deserve his position; both the Silver Dun winners too, and the first Blue are splendid birds in head. The Long-faced birds, too, make creditable classes. The awards in these classes were:—Silver Dun.—First-and-cup, second, and fourth, Clay; third Clulee; h.c., Godfree, Clay, Thompson, Mapplebeck, Gough, Slater, Wade, Breeden, Kemp. Blue.—First Hubbard; second Ludlow; h.c., Green, Clay, Yardley (2), Southall. Red Chequered.—First-and-cup Waterhouse; second and third Clay; h.c., Clulee (2), Yardley, Wade, Kemp. Blue Chequered.—First Clay; second Ludlow; h.c., Waterhouse, Green, Clay, Yardley (2), Ludlow. Long-faced.—First and second Rawnsley; h.c., Clulee, Wade, Lister. Silver Dun.—Hens.—First-and-cup, second, third, and fourth Clay; h.c., Moseley, Godfree (3), Clulee, Thompson, Waterhouse, Ludlow. Blue or Blue Chequered.—Hens.—First and second Ludlow; h.c., Grice, Waterhouse, Hubbard, Walton. Any other colour.—Hens.—First and second Clay; third Thompson; h.c., Lister, Gough, Copeman, Southall, Clulee, Ludlow. Silver Dun, hatched in 1880.—First Moseley; second Fellows; third Moseley; fourth Gordin; h.c., Yardley (2), Haywood, Lister, Mapplebeck, jun., Salmon, Moseley. Blue, hatched in 1880.—First Kemp; second Butler; h.c., Mitchell, Hubbard, Ludlow. Blue Chequered, hatched in 1880.—First Grice; second Yardley; h.c., Walton, Lund. Red Chequered, hatched in 1880.—First-and-cup Rawnsley; second Clulee; third, Kendrick, jun.; h.c., Thompson (2), Yardley (2), Wade, Slater, Green, Moseley, Holden.

Short-billed Frilled Varieties.—The two classes contain lovely collections. In the first-named Satinets are first (Wardle) and second (Bott), and a Bluetie third (Paget); h.c., Verdon (2), Yardley (2), Bott; c., Fulton. In the other class a Black Turbitten is first (Baker), and a Blondinette second (Yardley); third Verdon; h.c., Waterhouse (2), Wardle, Baker. These two classes fill thirty-five pens, and are a treat to any admirer of these eastern beauties.

Any other New or Distinct Variety.—First (Gatty) is a sandy Frill-back. Second (Chavasse) a Modena; a curiously marked bird of Runtish type. Third (Crofts) a Red Letz. 3979 (Naden) is a curious bird, black with white flights and a white line down its face; a cross apparently between a Dragoon and Beard; h.c., Gatty, Stevenson, Bulley, Yardley (2), Fulton; c., Ludlow.

The following were the principal sales up to the time of our going to press. Mr. Pilkington's cup Coloured Dorking cock, £15 15s.; Messrs. Smyth's h.c. Dorking cockerel, £10; Mrs. D. Lane's v.h.c. Houdan cock, 10 guineas; Mr. Rawnsley's first-prize Silver Polish cockerel, 10 guineas; Mr. J. Walker's second-prize Spanish cockerel, 10 guineas; Mr. Lyon's cup Black Red cock (a son, we believe, of the £100 bird of two years ago), £100 10s.; Mr. Harley's second-prize Black Red Game pullet, £25; Mr. Lyon's fourth Black Red cockerel, 10 guineas. We believe the same owner's cup cockerel in this class changed owners privately at 50 guineas. Mr. Kelleway's cup Black Hamburg cockerel, 10 guineas; Mr. Wyke's cup Turkey cockerel, 10 guineas.

BEXLEY HEATH POULTRY SHOW.

A LOVELY day induced us to visit this Show. It was held on Wednesday and Thursday last week, and the entries attained the respectable total of 653. The managers of many more pretensions exhibitions might well take a hint from the method in which this little Show is conducted. An able and enthusiastic Secretary and a Committee of thorough fanciers make a good foundation to start with. The penning was admirable, the heavier birds being in all cases in the lower tier. The feeding was all that could be desired, and the catalogue with the awards was in the hands of the public at 3 P.M. on the first day.

Dorkings, *Cochins*, and *Dark Brahmas* call for no special mention, but amongst the Light Brahmas the cock in the first-prize pen (Thurlock) was a very fine bird in all points, while the second-prize pen (Cobb) contained a pullet large in size and good in shape; but for her hocks and a very few dark feathers showing through her back she would not be easily surpassed. *Spanish* require no special mention. The winners in the *French* class were a very fine old pair of Mr. Howard's Houdans. *Game* had a large entry of fourteen, and the winners (Mercer) were a large reachy pair of Brown Reds, the cockerel being well pencilled on breast. In *Hamburgs*, Spangled or Pencilled (sixteen) the first (Bell) were an evenly marked pair of Golden-

pencils neat in head. The first-prize Black Hamburgs (Kelleway) were bright in colour and neat in comb and lobe. In this class the Judge disqualified a pen shown by H. Platten of Fakenham, Norfolk, for cut comb. *Leghorns* were a strong class of eighteen, first (Philcox) being very neat Browns, the cockerel very like the Palace winner. Second (Fowler) good Whites. *Andalusians* and *Minorcas* mustered twelve, first (Winser) being a nicely pencilled pair of the first-named sort; second (Wilson) Minorca chickens. *Polands* were eleven, and the first (Broad) went to a fine pen of White Crests. In Game *Bantams* (twenty) Mr. Anns took first and third with neat Black Reds and Piles; while second (Vigers) were Brown Reds rather large in size. In the Other variety Bantam class (twenty-three) the winners (Ayliffe) were Japanese, second (Geary) being Silver Sebrights. A good pen of Rouens stood first (Howard) in the Aylesbury or Rouen *Duck* class, while the Pekins mustered twelve pens of good birds, first going to Messrs. Fowler, and second to Mr. Kelleway. The Selling classes were well filled, and business appeared to be rather brisk. Local classes were added to the schedule this year, and were fairly good.

The *Pigeons* were a fine show, all the classes being well filled with birds of good quality.

HULL POULTRY SHOW.

WHEN we printed our report of this Show the following cup awards had not come to hand:—Mr. Ashburner's Brown Red Game cock took the £4 cup for the best cock or cockerel in the Brown Red classes. Mr. Dyson's yellow-legged Pile pullet (not the first-prize hen) took the cup for best Game hen or pullet, any other variety. In the Hamburg hen class the cup was won by Mr. Beldon's Silver-spangled hen.

In our report of the Light Brahmas, through a mistake in copying, our notes on the pullets were given as relating to the hens. Our readers will please substitute the names of Morgan (first), Norris (second), and Begg (third), for those given in our last issue, and read our comments on the hens as relating to the pullets. Our actual comments on the hens were as follows:—"First-and-cup (G. H. Wood) a shapely hen of good colour, but hocked. Second (Mitchell), a large hen, very rusty in colour. Third (Norris), good size, colour, and foot feather, but narrow in saddle."

VARIETIES.

ROOT SHOWS.—Messrs. James Carter & Co. announce, that instead of holding a show of pulled roots this year they are devoting prizes for acreage crops; they will, however, exhibit roots and other produce at the Smithfield Club Show, at the top of the arcade at the High Street, Islington, entrance of the Agricultural Hall.

— **PEA PRIDE OF THE MARKET.**—This new variety for farm and garden culture, that was raised at Messrs. Carters' Seed Farm at St. Osyth, and named "Strength," will be sold under the name of Pride of the Market. It is a variety of great promise, being dwarf, sturdy, very productive, with large pods, and peas of superior quality.

— **BRITISH BEE-KEEPERS' ASSOCIATION.**—At the last Committee Meeting of this Association held at 105, Jermyn Street. Present—Mr. Cowan in the chair; Rev. E. Bartrum, Messrs. Cheshire, Abbott, Hooker, and Rev. Herbert R. Peel, Hon. Sec. A large number of books presented by Mr. P. Jackson to commence the formation of an apicultural library had been already placed on the shelves by the kindness of the Jermyn Street Society. Mr. Cheshire was asked to act as Hon. Librarian, and to receive and arrange any further gifts that might be made. A second edition of "Modern Bee-keeping" is to be immediately published by Messrs. Longman, the first edition having very rapidly become exhausted. The Hon. Secretary stated that the diagrams were now included by the Education department as apparatus towards which grants are made for schools working in connection with the department. Several matters bearing upon the operations of the coming year, finance, and general routine occupied the remainder of the meeting.

— **ROOTS AT THE BIRMINGHAM SHOW.**—Messrs. Webb & Sons had a very fine stand. The specimens of Webbs' Imperial Swede were extremely fine. The prizes this variety has won are estimated at over £5000 in value, which include first and second honours at this Show for nine years in succession. Webbs' Prize Mangold, Col. North Yellow Globe, Mammoth Long Red, New Selection of Yellow Intermediate, Yellow-fleshed Tankard, and Webbs' Champion Yellow Globe Mangolds were all shown in splendid condition. White-fleshed and yellow-fleshed Turnips were also fine. Potatoes added considerably to the display. Webbs' Improved Schoolmaster was

conspicuous, and other leading varieties were admirably represented. Although Messrs. Sutton were not exhibitors this year, yet the produce of their seeds in the root classes was of great excellence. The very fine Mammoth Long Red and Berkshire Prize Yellow Globe Mangolds, and Suttons' Champion Swede, with which Mr. R. Webb, Beenham, secured Messrs. Proctor & Ryland's cup, were splendid. Equally meritorious was the collection of six roots each of Suttons' Mammoth Long Red, Suttons' Berks Prize Yellow Globe, and Suttons' Golden Tankard Yellow-flesh Mangolds exhibited by the same grower, and which gained him the cup in Class 3. Very fine specimens of Suttons' Yellow Intermediate, grown by Mr. W. W. Champion, and handsome roots of Berks Prize Yellow Globe, grown by Mr. R. Webb, worthily secured first and second honours while Mr. J. Perry's twelve specimens of Suttons' Champion Swede, which took the cup in Class 9, were of remarkable merit.

— **CANADIAN PRODUCTS.**—Some extraordinary roots and vegetables from Manitoba and Ontario are on view at Mr. Cuthbert's, seedsman, Clayton Square, Liverpool. Some of the roots are on their way to the Smithfield Club Cattle Show, London. It appears that in addition to those from Manitoba, Messrs. Rennie, seedsmen, Toronto, have sent an assortment of Pumpkins, amongst them being a Monarch Squash weighing 313 lbs. The plant that produced the fruit was planted on the 1st of May, fruit cut on the 6th October, thus showing an average growth of 2 lbs. per day. Also a very large red Mangold, over 3 feet 6 inches in length and nearly the same in girth. It is ugly in shape, but weighs 73 lbs. There is a Yellow Globe, weighing 58 lbs., Mangold Citrons 33 lbs., and immense examples of Beet Carrots, Parsnips, Vegetable Marrows, Onions, and Potatoes. Fifty varieties of Apples are on view, which are of fine size, colour, and shape. Some Newtown Pippins weighing 21 ozs., and Gloria Mundi are grand amongst many others.

— **THE death** is announced of Mr. R. O. Pringle, at the age of 62, who was for many years, and at the time of his demise, editor of the *Irish Farmers' Gazette*. He was one of the best authorities of the day on all subjects connected with land tillage, cattle breeding, and farming operations generally. His contributions were of great value to the farming classes, and the almanack with which his name was identified was greatly prized.

ARTIFICIAL COMB FOUNDATION.

YOUR correspondent "A. P." in the Journal of the 18th ult., page 474, referring to comb foundation, states that "if the foundation be proved to be of substantial advantage in apiculture, a successful way of using them in straw hives will be invented and adopted." From this statement it may be inferred that foundation has not hitherto been proved to be of substantial advantage, whereas it has been of such immense advantage that bee-keeping would not hold the position it does now without it. I have now used foundation in my hives for sixteen years, and certainly should not like to do without it. With foundation straight combs are the rule, whereas straight combs without foundation are an exception. Not a single comb in my apiary has been worked without foundation, and I can take out any frame and put it into any hive with the certainty of its fitting. I have never seen it possible to do this in hives where foundation had not been used.

I have long since discarded straw hives, because bees in such hives are not under the complete control of the bee-master, the manipulations are much more laborious, and the quality of the honeycomb produced is at best only second-rate, but when I did use them I fixed strips of foundation in a different way from that suggested by "A. P." Some years ago I introduced a straw hive with a flat crown of wood, which I gave to cottagers to induce them to adopt a more humane system of bee-keeping than they had hitherto been accustomed to. On the crown could be placed wooden boxes or supers. The under side of the crown and the under side of the top of the super had saw cuts in them to a depth of one-eighth of an inch, and an eighth of an inch wide. The distance between these saw cuts in the straw hive was $1\frac{1}{2}$ inch, which is the proper distance for brood combs, and the distance in the supers was 2 inches, because it is better for the honeycomb to be thicker, as a less quantity of wax is used to fill up a super with thick combs than would be the case if the combs were only $1\frac{1}{2}$ inch apart.

When it is required to fix the foundation, it is cut into strips

not more than from 4 to 6 inches in depth, the hive turned up, and a strip of the proper length dropped into the first groove. The hive is then tilted up from front to back, and having previously heated some wax in a smelter, the long spout of the wax smelter is brought near the upper end of the groove, and a small quantity of wax is allowed to run down the groove on one side of the foundation, which securely fixes it in its place. When the wax is firm, proceed in the same way with the next strip, and so on until your hive is full of foundation. If properly done and the wax hot enough there will be no danger of the foundation falling out. The boxes were treated in the same way. I have for some years used the Stewarton hives, and have always fixed the foundations in this manner. "A. P." recommends the foundation to nearly touch the cross sticks, which makes me believe he has not tried it. The foundation should not touch the sticks within half an inch, or the result may be buckled combs, which frustrate the object the bee-keeper has in view.

We have heard much lately about straw hives, but how is it we never see any honey produced from these hives at any of the numerous shows held throughout the country? The only answer is that the straw hivists are afraid with their irregular combs to compete with the beautiful straight combs now produced by those who have the moveable-comb hive. If a bee-keeper wishes to obtain the best article in the shape of honey he must adopt the most improved methods of production, and he will find that unless he uses comb foundation he will not be able to compete with his neighbour who does. Comb foundation is very different from what it was some years ago; it has been greatly improved, and the price is so low that it is certainly within the reach of all. That it has been and is of substantial advantage has been proved long ago, and I am sure no one who has used it properly would ever think of doing without it. "A. P." says, "I shall be pleased if all the schools give them a fair trial next season, and record their results." Has "A. P." only just heard of foundation? and does he not know it has been employed by advanced bee-keepers for a great number of years, and by nearly all bee-keepers using moveable-comb hives now? I could record the results he asks for, but it would be a repetition of what has been previously stated by others in this and other journals, not only showing that it is useful but indispensable.—THOS. WM. COWAN, *Horsham*.

MR. PETTIGREW'S CHALLENGE.

IN a late issue of our Journal my friend Mr. A. Pettigrew calls on "PERTSHIRE" to come forward and compare results with his Carluke friends. As, owing to the attack of foul brood which I lately described I am practically "out of the running" this year, I showed the challenge to a neighbour of mine, a working mason, who may be taken to be a fair representative of the modern school. My friend, William Mann, is no stranger to the skep, having practised that system for years. He has, however, gone in strongly for the bar-frame system as the most profitable. In his reply he says:—

"I see that Mr. Pettigrew has published some wonderful results from a skep at Carluke. I had thought that the time for pitting skeps against bar-frames was over long ago; but if Mr. Pettigrew chooses I am prepared to set aside six of my best hives against any six of his during next season, the one who fails to show the best results from any one of his six stocks to forfeit one of his stocks to the other. I do not profess to be an expert like Mr. Pettigrew; but that will give him the better chance of getting a bar-frame hive to learn upon. I have twenty-four stocks all in splendid condition. I raise all my own queens from my choicest stocks, and I am this winter venturing to keep spare queens in case any should be required in spring. I do not keep a record of every hive, but I did of one this year. It gave me 122 lbs. comb honey in 1 lb. sections, 30 lbs. extracted honey, and has over 40 lbs. left to winter on; yet I consider this has been a poor honey season. I sold the honey taken from this hive for £9 11s., and have my stock left to me well supplied.

"In 1878 I took from one hive 173 lbs. in supers, the hive being only one of several swarms run off a skep in the same year. I had only four weak stocks to commence with that year, but I increased to eleven, sold 600 lbs. of honey, and left enough for winter stores."

I may add that Mr. Mann makes all his own hives, and though devoting great attention to his bees, I do not think he lost a day's work at his trade this season.—WM. RAITT.

SUCCESSFUL BEE-KEEPING.

I SEE in your valuable Journal of October 28th, that Mr. Pettigrew invites comparison of his straw system with the bar-

frame or Stewarton system. I have been a reader of the Journal for many years, and have read with interest what has been advanced on both sides all tending to the advancement of bee-keeping. I admit Mr. Pettigrew has done much for the cottager by the advocacy of large hives, but surely he must see the great advantages the new system has over the old straw hives. Your correspondent has a good right to praise his own system, but with your permission I will give one instance that came under my own observation of the benefits of the Stewarton system in Arran this most productive season. From one stock James Crawford, a mason, obtained the following results: Old stock, 140 lbs.; top swarm, 187 lbs.; second swarm, 154 lbs.; total, 481 lbs.—JAMES ANDERSON, *Ryeside Cottage, Dalry, Ayrshire*.

OUR LETTER BOX.

Andalusian and Angora Rabbits (A. W.).—We are unable to inform you where they are obtainable; those who have them for disposal would do well to advertise them.

Fowls and Foxglove (Baltimore).—Although we have not had experience of fowls being injured by eating Foxglove, still no doubt it would have such an effect as you describe. The following extract from Dr. Hogg's "Vegetable Kingdom" may be of interest to you:—"If the leaves are rubbed between the fingers they emit a nauseous odour, which is dispelled in drying, and they have a bitter and slightly acrid taste. The plant is narcotic, sedative, and diuretic. When administered in small doses it has not any marked effect on the system, but in large doses it produces nausea, vertigo, headache, dimness of sight, secretion of saliva and urine, vomiting, frequent action of the bowels, increased pulse and confusion of thought, and convulsions. Its medicinal properties were first brought into notice by Withering, and, when judiciously administered, it has proved valuable both as a diuretic and for its sedative influence over the circulation. It is highly useful in dropsy, in controlling the action of the heart, in aneurism, hypertrophy, and enlargement of the heart, palpitations from gouty or rheumatic irritation, and in various forms of hemorrhage. It has also been prescribed in mania, epilepsy, spasmodic asthma, and whooping cough. But, as a medicine, it should never be administered unless by a skilful and practised hand, because of its extreme activity, and the dangers resulting from an imprudent use of it; and one of its peculiarities is that, after having been given in moderate doses for several days without apparent effect, it sometimes acts suddenly, with an accumulated influence, even to the danger of life."

Feeding Bees (G. S.).—You ought to have fed the bees freely in September, so that the stock at Michaelmas weighed at least 20 lbs. without the hive, and then have left them quiet and well protected through the winter. If the colony is much below that weight now you can only continue giving syrup during mild weather; if the hive is about the weight named feeding will not be necessary, but the hive must be well covered to keep the bees as warm as possible.

REMARKS.

21st.—Fine, bright, and cold.
22nd.—Very cold; fine with bright sunshine; slight fog in evening.
23rd.—Overcast morning; slight rain at noon; sunshine between 1 and 2 P.M.; damp evening.
24th.—Rain in morning; fair afternoon; much warmer day.
25th.—Stormy, much wind; showers and very bright sunshine at intervals; starlight evening.
26th.—Rain in morning; afternoon and evening fine.
27th.—Very fine spring-like day.
Temperature on the whole near the average, but varying very much; that at 9 A.M. on 26th, 55.5°, was nearly 30° above that of the 22nd.—G. J. SYMONS.

COVENT GARDEN MARKET.—DECEMBER 1.

IMPORTATIONS of American Apples have been large this week, making fair prices. The first cargo of St. Michael Pines is to hand, but samples are inferior. Trade quiet.

PEARS.

FROM the peculiar results of the last four or five years wall trees would appear to have become quite indispensable to ensure a crop of Pears. Year after year the pyramids and espaliers blossom freely, but spring frosts and cutting winds destroy the flowers, so that without the wall trees a supply of good fruit cannot be relied on. But the wall trees seldom fail to afford a fair quantity of fruit, and this year the crop was abundant. The trees are still young, hardly any of them having yet fully covered the allotted area of wall space, yet most of the palmette verriers on west and north aspects had good crops, and the diagonal cordons upon an east wall were with few exceptions crowded with fruit. The wall of palmette verriers is a fine sight, for the trees are of uniform size and form, the lower branches are fast approaching the top of the wall, and the spurs are yearly becoming more fruitful. Yet the cordons are much preferable, beginning to bear fruit so soon after planting, that much of it has frequently to be picked off for the first year or two to avoid damage to the trees. They are easier to manage and may be planted against any space of wall or building, even one or two trees being useful, for a single cordon when fully grown will afford several dishes of fruit, and it only requires a strip of wall 18 inches wide. If you can afford space for a dozen or two you have only to make as many marks as you have trees, from top to bottom of the wall at an angle of 45°, and 18 inches apart, then prepare the soil, plant the trees—one to each mark, up which you must train the stem. Can anything be more simple? I can add that certainly nothing can be more useful. There stand the huge pyramids, each of them large enough to bear a bushel of fruit, and yet the crop is lost year after year, while the little cordons upon a wall facing due east go steadily on year by year bearing fruit, which becomes finer and more abundant as the trees gain size. Many a pleasant and profitable hour have I spent this year along this wall of sixty cordons; nor did the pleasure end with the gathering of the fruit, for subsequently in the fruit room its time of ripening, comparative value when ripe, and keeping properties have all been watched and noticed, and the season is now sufficiently advanced to enable me to submit a list of some of them for the information and guidance of your readers. First come the summer Pears, of which there were four varieties ripe in August, the first being

Summer Doyenné, better known to many fruit-growers as *Doyenné d'Été*. The first dish of fruit was ripe on August the

3rd, and it continued to afford a supply till the 19th. This was managed by first gathering the fruit at the top of the cordon, where it is always ready first, and the ripening process continues with singular regularity downwards to the bottom. The fruit is small but handsome and highly coloured, sweet and juicy but not rich.

Citron des Carmes.—This was two days later than *Summer Doyenné*, to which it is very similar in flavour. Its larger fruit spoils quickly, but I had a few dishes of it, which proved very useful.

Beurré Giffard.—This came in time to continue the supply, the first dish being ripe on August the 19th. Its very handsome yellow rosy-cheeked fruit has a fine flavour, and is very juicy and sweet. I value it highly, regarding it as the first really good Pear, but like other early varieties its season is somewhat brief, this year lasting only twelve days.

Jargonelle.—The first dish of this delicious old favourite was ripe on August the 21st, and the supply continued for a fortnight.

Summer Beurré d'Arenberg.—A fine and abundant crop, the first of which was ready for use on August the 30th. I find the following note of it in my fruit book, written after tasting the fruit this year. "Delicious! very juicy, sweet, melting, with a brisk refreshing acidity. A most valuable variety, forming an admirable succession to *Jargonelle*." There was a good supply of it for a fortnight, which may be named as the general duration of early Pears.

Desiré Cornélis.—This ripened a few days earlier than *Williams' Bon Chrétien*. Its fruit is equally fine, and it possesses all the good qualities of a first-class Pear. It first bore fruit here on a pyramid some five or six years ago, and was so good as to induce me to assign it a place amongst the most select varieties. The growth is so robust that it will probably prove a useful hardy variety generally.

Williams' Bon Chrétien.—Not ripe till September the 12th. Fruit large and excellent. A palmette verrier on a north aspect kept up the supply of fruit till October.

Colmar d'Été.—This fruited here for the first time this year, and the first dish of it was ready for table September the 18th. It has a pleasant musky aroma, and is brisk, sweet, and juicy.

Beurré de l'Assomption.—This also fruited for the first time, and I was much disappointed with it. The large fruit was coarse, gritty, tolerably sweet and juicy, with very little aroma. Quite a second-rate variety in this soil.

Beurré d'Amanlis.—Fine large handsome fruit, still of a pale green hue when ripe. Delicious, very juicy, buttery, sweet with a pleasant acidity. First dish ripe on September the 30th.

Madame Treve.—As remarkable for its large size, fine form, and high colour, as it is for sweetness, juiciness, and aroma. It was not ripe till the first week in October, and did not keep good longer than a week. This fruit was from a cordon. Some other fruit off a pyramid was equally large, but was deficient in colour and of so poor a flavour as only to be useful for stewing.

Doyenné Boussoeh.—Very large and remarkably handsome fruit, which was ripe on October the 1st. It was tolerably sweet and juicy, but quite second-rate; nor was its poor flavour peculiar to the year, for after fruiting it for several seasons both against a wall and out in the open garden, I am sorry to record its invariable inferiority.

Jersey Gratioli.—This, too, was ripe on October the 1st; and although decidedly superior to Doyenné Boussoch in flavour, I by no means regard it as an indispensable variety.

Fondante d'Automne.—Once more I gladly record the invariable excellence of this delicious Pear. There is none equal to it in its season, which begins about the last week in September and continues till the middle of October. It is tender, juicy, extremely melting, very sweet, and has a rich flavour with a delicious aroma. It is very hardy and prolific, bearing fruit early, and continuing fruitful.

Jalousie de Fontenay.—Ripe the first week in October. Pleasantly sweet and juicy, but quite second-rate.

Comte de Lamy.—This forms an admirable succession to Fondante d'Automne and is equally good. The fruit is not large, but its singular richness well atones for this. The first dish of it was ripe on October the 15th. I have often had good crops of excellent fruit upon a pyramid; this year only the cordon had a crop.

Thompson's.—This was ripe on October the 14th, and continued good for three weeks. It is a most excellent Pear, remarkably juicy and rich.

Baronne de Mello.—The fruit was very handsome, quite covered with an orange russet. It was sweet, juicy, and of pleasant flavour, but not rich. Ripe the second week in October, and was good till November.

Doyenné du Comice.—An abundant crop of its fine large fruit both upon a cordon and a palmette verrier, but there was none upon the pyramids. It was ripe on October the 9th, and was as usual excellent. It is one of our very best Pears, and should never be omitted from the choicest selection.

Beurré Superfin.—The fruit was very large with singularly long stalks. It was ripe the third week in October, and proved very juicy, sugary, rich, and delicious. A fine Pear of great excellence.

Pitmaston Duchess.—The tempting description published of this Pear induced me to plant several trees of it, but I regret to say it has not answered my expectations. The magnificent fruit was ripe the middle of October, but was so acid as to be decidedly unpalatable.

Beurré Bachelier.—Fine large fruit of pleasant flavour, sweet but not rich. It was ripe on November the 16th. Fruit off the same cordon was not ripe till February the 5th in 1875.

Napoleon.—Ripe the second week in November. Very juicy, sweet, and rich. An excellent Pear.

General Todtleben.—A remarkable Pear with very large and long fruit, some of the stalks, too, being quite 3 inches long. It was ripe early in November, but I did not taste it till November the 15th, and to my surprise found I was too late, every fruit then being overripe; but one or two still retained much richness, and its peculiar perfume and the rosy-tinged flesh proved it to be the true variety.

Dana's Hovey.—There was an abundant crop of this delicious little Pear, which was ripe early in November. Very rich, juicy, sweet, and with an agreeable musky flavour.

Passe Colmar.—An excellent Pear of delicious flavour, very juicy, sweet, and rich. A fine crop of it, ripe the second week in November, and keeping well.

Beurré Diel.—Ripe early in November, of fine flavour but not very juicy. A useful old variety, very prolific.

Huyshe's Victoria.—Handsome fruit, bright yellow dotted with russet spots, and of a dark red on the exposed side. Ripe mid-November; very juicy and buttery, but a little deficient in sugar this year. A useful Pear and good cropper.

Alexandre Lambré.—Ripe early in November, of fine flavour, but not juicy. An inferior variety.

Alexandre Bivort.—Handsome fruit of medium size, very rich, sweet, with a brisk but delicious acidulous flavour, and so juicy that the juice drops from it as it is cut or eaten. An excellent Pear, ripe the middle of November, and keeps good for a long time.

Maréchal de Cour.—Ripe on November the 16th. Fruit very large, long, and handsome. Most delicious, juicy, aromatic, and rich. A grand Pear, with what is justly termed a sprightly flavour.

Emile d'Heyst.—A delicious Pear, very rich, juicy, sweet, and highly perfumed. The first dish of an abundant crop

of its very handsome fruit was ripe the second week in November.

Beurré d'Aremberg.—This is another of our best winter Pears, which this year was ripe by the middle of November. The fruit is of medium size, it keeps well, and is very juicy and richly flavoured.

Deux Sœurs.—The long large fruit is not handsome, but it is very good, of fine flavour, melting and buttery, and very sweet. It was ripe on November the 15th, and was only good for a fortnight.

Josephine de Malines.—This had moderately large fruit, which was ripe in the second week of November. It has a delicious delicate flavour, and what Dr. Hogg has aptly termed a "high rose-water aroma." Its yellow flesh tinged with red also helps to render it a distinct Pear easy of recognition.

Glou Morceau.—I tasted the first fruit of this on November 29th. It was then so far ripe as to yield to pressure, but would evidently be better if kept for another week or two. The flavour was brisk and pleasingly acidulous yet rich, and it was very juicy. A most valuable Pear, which has come slowly into fruiting, but its numerous blossom buds give pleasing promise of an abundant crop next season.

The foregoing brief descriptive notes may be taken as a safe guide for light soils. Experienced pomologists will doubtless observe the remarkable earliness of many Pears that is so peculiar this year. It is not merely a difference of days but of weeks and months. I cannot account for it, and can only regret that so many of the best Pears are ripe at the same time instead of following in succession as in ordinary seasons. The list is by no means to be regarded as containing the only good varieties, although it contains so many that I at any rate have no reason to agree with those who assert that we have very few really good Pears. Several well-tried favourites had no fruit this year, others are not yet ripe and were therefore left out; but I may usefully add the names of such excellent varieties as Comte de Flandre, Millot de Nancy, Jewess, Besi Vaet, Marie Louise d'Uccle, Winter Nelis, Nouvelle Fulvie, Duchesse d'Orleans, Knight's Monarch, Urbaniste, Red Doyenné, Doyenné Defais, Louise Bonne of Jersey, Madame Millet, Easter Beurré, and Beurré Clairgeau, which last as usual had an abundant crop of large fruit brilliantly coloured, and so good in flavour as to cause it to be highly valued. Let not my addendum be regarded as unreliable. I have repeatedly fruited all of them, and not one is lightly recommended. To owners of small gardens requiring a select dozen I may name Beurré Giffard, Summer Beurré d'Aremberg, Désiré Cornélis, Fondante d'Automne, Comte de Lamy, Doyenné du Comice, Dana's Hovey, Passe Colmar, Alexandre Bivort, Glou Morceau, Josephine de Malines, and Madame Millet.—EDWARD LUCKHURST.

LILIUM LANCIFOLIUM (SPECIOSUM).

MUCH has lately been published about Liliums and their being grown out of doors with success, as if it were a new discovery. I remember gardens, one especially, where in 1844 to 1848 the varieties of this species were grown in the borders in masses of a dozen bulbs together, and also in rows in the kitchen garden. At that time, as old gardeners will remember, bulbs were in great demand. Who that has ever had the pleasure of going round the late Mr. Groom's garden at Clapham can forget the appearance of his show house in the early autumn with Liliums, or the large bed planted with them in his garden? Large numbers of fine bulbs which were not required by Mr. Groom used to pass into the hands of a well-known florist of that day, and the way they were managed was as follows.

In order to increase the stock numbers of scales were carefully taken off the outsides of the bulbs, but not to reduce them too severely; these scales were planted in a prepared bed in the kitchen garden. The soil was removed a foot deep, and the trench thus made was about three-fourths filled with a compost of ordinary peat, decomposed cow dung, leaf soil, and sharp sand well mixed. On this a thin layer of silver sand was spread, and the Lily scales were inserted upright covered with 2 or 3 inches of soil, and a temporary frame was placed over them to throw the wet during the winter. This was removed in the spring, and in the following October a fine lot of young bulbs of various sizes were carefully taken out and afterwards planted in rows. The largest and plumpest of the bulbs, which had been deprived of their scales,

were placed in a wheelbarrow and taken to the flower borders. When the head gardener had marked out the situations a man followed and dug a deep hole, in which was thrown a shovelful or two of old partly decomposed cow manure which was mixed with the soil, then followed a few shovelfuls of the compost above mentioned, and on this the bulbs were planted, then more compost, and finally the ordinary soil. A label was placed to each clump. The small bulbs were next attended to. A trench was made as for Celery, manure was dug into the bottom of the trench, the compost was wheeled into the trench upon the manure, and the bulbs planted in rows. I have frequently planted small bulbs the size of walnuts, and taken them up in October as large as a cricket ball and almost as solid. The past season a friend of mine has been trying a similar practice with *L. auratum*; he was successful, and says he had one or two bulbs as large as a quart jug. He also mentioned having two varieties of *L. auratum*; one blooms five weeks before the other, is dwarfer, and not so good as the later one.

I have often heard of late years that the white *L. lancifolium* or *L. speciosum album* is gradually dying out. I am now able to say something on the point. Old gardeners who recollect the handsome *Liliums* grown thirty or forty years ago in pots 10 or 12 inches in diameter, the plants being 5 or 6 feet high and bearing twenty or thirty large blooms, will be able to understand how pleasing it was to me to see plants of the varieties *album*, *rubrum*, and *punctatum* in such pots in the garden of Sir Humphrey Trafford, Trafford Park, some plants with thirty to forty flowers, and one specimen of *L. lancifolium album* had fifty blooms. I had not seen *Liliums* grown so well for a very long time. I believe much harm is done by spring planting and by keeping the bulbs too long out of the ground. Another cause of injury is stowing the pots away anywhere when the plants have flowered until next February or March; the soil is then shaken from the bulbs, and as fresh fibres have been produced they are broken in the operation. Is it surprising that under such treatment the constitution of the plant is ruined? If you desire to have good bulbs and good blooms pot or plant the *Liliums* from the end of October to the end of November at the latest, and if manure is employed let it be placed deeply, so that it is not in contact with the bulb.—N. I. D.

NOTES ON HARDY FRUITS.

I AM glad that "A. M. B." intends to give the Apple called Stirling Castle a trial. I am sure it will give satisfaction. I have this year added three fresh Apples on trial to my stock—namely, Yorkshire Beauty, Golden Noble, and Waltham Abbey Seedling. The object of my experiments in hardy fruits is to find those varieties which combine beauty and utility. I mean by the former, beauty of shape if not of colour; and by utility I mean size as well as good flesh, good keeping, good eating, or good cooking qualities.

One thing let me particularly impress on planters just at this time in regard to pyramids: Do not plant deeply; do not plant your tree so low as to cover with earth the part where the tree is grafted. If you do in the case of Pears this result will follow—the Pear stem will send out roots, your tree will grow fast and be perfectly barren for years; it will then be, "Plant Pears, plant for your heirs." The whole idea of a pyramid will be upset: the lower branches will die, but a huge growth will take place high up, and instead of a pyramid you will have a tall tree, in fact a standard—just what, if you delight in pyramids, you do not want. Another hint: Be sure and do not allow your man to cut off any of the lower branches. They all wish to do it—all of a less high caste as gardeners, in order to work under the tree better. This working under it, by the way, is just what is not wanted. Let the soil be only turned over a few inches deep, so that no root is disturbed, or, worse, dug up. If it be, then down go the roots into the bad soil below, and your hopes will be frustrated. Also beware lest your man dig up the roots between the Raspberry canes. I have seen in former years barrowfuls of roots dug out and removed, and the fruit deplorably injured. A hoe is all that is necessary to work between the rows. These may seem homely hints; and some, perhaps many, readers will say, "We knew all this before." Granted; but some may not, and on homely hints being taken success in gardening depends. I have after long trial given up growing Plums as pyramids. I have watched several gardens, some near London, others in my own district, and find the result the same—no crop, only at best a sprinkling. I train my Plums to walls, or, lacking room, give them to friends who have room.

With Apples I consider myself very fairly successful, and indeed we need great success if we are to compete with any chance against the Americans. Only recently I was in Bath and sought out a large fruit shop and began talking to its proprietor. I said, "You have fine Apples there." He replied, "Oh, yes! Americans.

They call them Red Baldwins. We cannot get English Apples people like so well." The same thing I observed in a Wiltshire town recently. What we ought to do, therefore, is to grow varieties of Apples which are large and handsome and of good flavour, or we shall be beaten out of the market. One or two remarks about American Apples: They will not grow in this country so fine as in America. Then I have never tasted any of the tinned American Apples which have a fine or even decided flavour. The fruit looks well in tarts, but it is tasteless; no real good flavour, not to be compared with our English varieties. If we grow abundantly—yes, and superabundantly—fine-coloured, large-sized, good-keeping, and good travelling Apples, we shall be able to hold our own. Plant each year some fresh trees of varieties you have tried yourself or know others have tried and approved. There are thousands of Apple and Pear trees which are only fit for firewood—lichen-covered, miserable, old trees, which are allowed to remain because twenty or thirty years ago they produced "such fine fruit and such a lot of it."

One other hint. I grow nothing but pyramids, but I grow them naturally. I neither summer-prune nor winter-prune. As they come from the nursery in proper form so they grow on. If a branch grows across I remove it; that is about all I do. The result is that the trees keep thin, and sun and air penetrate through them always; hence also fruiting spurs gradually but surely form. I have well-grown trees natural-shaped and thin, not stunted thickets, barren of all things except constantly increasing sticks fit only for stakes for flowers in pots.

One word more and I have done. I was obliged, from liability to take cold, to give up keeping fancy Pigeons. I dared not go all weathers into a draughty Pigeon loft. The doctor shook his head and said "No" so decidedly that appeal there was none, and to be a Pigeon fancier and not constantly be among your pets is miserable work. I then turned as a hobby to hardy fruit culture, and now for several years I have found it most interesting, and heartily recommend it to those situated like myself.—WILTSHIRE RECTOR.

P.S.—When you plant a tree I do not recommend placing long litter at once over its roots, as I think in mild rainy weather—and planting weather must be mild—it creates too much damp for the good of the said roots. However, have some near each tree to put on when hard weather comes, and again remove it when soft wet weather returns. By this means you benefit the tree, and you catch an enormous number of slugs, for in frosty weather they crawl under the litter for warmth, and on raising it you will find them on the ground. I have this day caught more than a dozen under some of my trees, where they had secured themselves, as they thought, a snug and warm berth for the winter.—W. R.

THE BLACKWOOD TREE OF AUSTRALIA.

THIS very handsome and valuable tree, *Acacia Melanoxylon*, cannot be well known in Britain, as it is not mentioned in Johnson's "Gardener's Dictionary." A plant of it grew for about a dozen years in the garden of Cromla, Corrie, Isle of Arran; but the situation was unfavourable, the ground being very wet. It was at length transplanted, but died. In the month of September last year a friend presented me with a fine young plant, which I placed in the same garden in Arran. Last winter was the most fatal to shrubs that I have known, but the *Acacia* was uninjured. This year the same friend has given me another plant of this noble tree, which I have been permitted to plant in one of the best situations at Brodie, Arran. As it is of very rapid growth, it and the one at Corrie will soon become a tall and very ornamental tree.

The following note regarding it from a report by Baron Ferdinand Von Mueller, F.R.S., kindly sent by him to me, will interest:—"The bark of this highly valuable timber tree has generally gone to waste, after from the logs the splendid wood was obtained. The bark is, however, very rich in tannic acid, and ought not to be left unutilised, although no Blackwood Trees should be sacrificed for the sake of their bark alone."

The fine Ferns *Dicksonia antarctica* and *D. squarrosa*, though as usual unprotected last winter, are in their wonted health.

The beautiful Gum Tree beside them, also never injured by frost in Arran or at Roseneath, Gare Loch, is, I believe, *Eucalyptus amygdalina*, as it appears to be identical with plants of this species raised by me from a packet of named seed which, along with nineteen others, I received from Baron Von Mueller. There is a tree of this species in Victoria 450 feet in height. Will it ever attain to this height in Arran?—DAVID LANDSBOROUGH.

HOLLOW CELERY.—This year I have about seven hundred Celery plants and out of this number I have no more than two

dozen sound heads. Some writers say over-feeding with liquid manure and a check to growth when the plants are young will cause the stems to be hollow, or allowing the plants to remain in the beds too long before planting them in their permanent place. My plants were neither fed with liquid manure nor checked when young. I have some planted with plenty of manure in the trenches and others without any, and I find all the produce is in the same state. Should this meet the eye of gardeners who have been in the same fix, I shall be glad if they will give me their opinion on the subject and suggest a remedy.—F. T.

FORCING STRAWBERRIES.

THOSE of your readers who have been preparing Strawberry plants for forcing will now have them in a dormant state, and will be probably contemplating placing a few in their forcing quarters. If it is not absolutely necessary to have them in at a particular time I would advise delaying placing them in heat as long as possible, as there is little to be gained by starting the plants into growth very early. I have started numbers in December, and others not until the end of January, and by the end of March the latter were as early as the former, and certainly superior in the quantity and quality of the fruit. Many of the flower shoots which readily commence growth in February and March, scarcely move in December and January. December must certainly be regarded as a precarious time to begin Strawberry forcing; January, especially about the end, is better, and later is better still. However, as many growers cannot select their own time, the best must be made of them at all seasons. Before placing the plants in heat it is of little consequence how much cold and bad weather they are exposed to so long as frost does not break the pots. Except to guard against this I never protect any of my Strawberry plants in winter, and the crop which I have obtained from them afterwards has never led me to suppose that this treatment is wrong. As each batch is taken in to force, the dead leaves are removed from the crowns, the surface soil is cleaned and the pots washed. I never plunge the pots in bottom heat, and I find the plants grow perfectly well without this assistance. At first they are placed anywhere about the floor of a house where the temperature averages about 55°; and after they have been a week or two there, and when they have commenced growing, they are shifted as much into the light as possible, and in a slightly higher temperature. As soon as the flower buds appear 65° is not too much heat for them, and it should not average more than this throughout all their growth. I never employ saucers or turves beneath the pots, but from the time the plants come into bloom until the fruit is gathered they are watered twice daily, and insects or mildew rarely trouble them.

In growing Strawberries in pots much depends on the supply of water. If the soil and roots are kept moderately moist at all times success will be certain. As the blooms open and the fruit swell liquid manure is given every other day, but apart from this they are treated similarly when the fruit is ripening and before it was formed. I never dry-off the plants, withhold water in the slightest, or increase the ventilation greatly to gain more flavour, as this would be sure to check the later fruit. Aphides are sometimes troublesome. For these and other insects the plants should be carefully examined before the blooms open, as they cannot be destroyed readily afterwards without injury to the flowers. A thorough syringing is one of the best modes of cleaning the plants, and this should be given before the flowers open, and again immediately after the fruit has formed. During the time the flowers are open it is an advantage to brush them over gently with a feather or soft hair brush to spread the pollen, and they should not be exposed to cold winds at this time, or many deformed fruits will be the result. As soon as the fruit has formed the smallest should be removed, leaving only about twenty-four of the best-formed and most prominent. I have allowed many more than this number to remain on sometimes, and they swelled very well, but a regular crop all through of twenty-four fruits to a pot is profitable. Those who force thousands of plants may take in hundreds at a time, and those who only grow hundreds may find a few dozens enough to introduce to heat at intervals according to the demand.—A KITCHEN GARDENER.

THE WEATHER IN IRELAND.—The weather here for some time past has been extremely mild for the time of the year. The days have been so genial as to remind us of the months of April or May. For ten days the mercury of my outdoor thermometer never fell below 46° night or day, and more generally, as at present, it stood at 56° Fahr. Outdoor Chrysanthemums, double Daisies,

Wallflowers, Anemones, Crocuses, Stocks, and Pansies, are still bright and cheerful; and the spring flowers are making great progress, that will be disastrous if severe weather comes by-and-by. The same is true of grass and the early buds on deciduous shrubs and fruit trees.—W. J. M., *Clonmel*.

OXFORD BOTANIC GARDEN.—No. 3.

NYMPHÆAS.

HAVING briefly referred to the chief interesting portions of the history connected with this Garden, a similarly cursory description of the most remarkable plants in the collection will indicate how well the various divisions of the vegetable world are represented. As will have been gathered from preceding remarks, the garden is not extensive, neither is the accommodation for plants under glass very great, and it is surprising that so large a number of species can be maintained in such satisfactory condition as that which marks the majority. About ten houses are devoted to tropical and other plants requiring such protection; most are of moderate size, and some are rather old, so that the successful treatment of their occupants is by no means easy. A new and commodious range of houses would enable the collection to be considerably increased and improved, and add much to the renown of the Garden, for many visitors are greatly disappointed in the appearance of the present structures. Herbaceous and hardy plants are well represented, some being arranged in their natural orders, and others according to the Linnean system, while against the walls are many rare and curious trees and shrubs too numerous to particularise.

The Oxford Botanic Garden has long been noted for its collection of tropical aquatic plants, and consequently it was the house devoted to them that I was most desirous of visiting, and to which I first directed my attention. Although I am familiar with the beauty of such plants, I was totally unprepared for the magnificent display of those most charming of aquatics, the Nymphæas, which there greeted me. A large tank of oblong form was occupied with all the best forms of the genus, the majority in flower rendering the surface of the water bright with diverse shades of blue and rose, relieved by a few white blooms and the rich green elegant foliage. The flowers were very numerous, most of them emitting a powerful and agreeable fragrance, the general effect being heightened by the arrangement of tall graceful plants around the margins of the tank. This house is incomparably the most attractive in the Garden, and those who are fortunate enough to see it at such a favourable time as I did will not readily forget it. There are, perhaps, comparatively few private gardens in Great Britain where adequate accommodation can be provided for Nymphæas in large numbers, but there are many in which some may be advantageously grown either in a specially prepared heated tank or in large shallow tubs. A regular temperature between 75° and 80° both in the water and the atmosphere, good turfy loam with a small proportion of well-decayed and dried cow manure suit the majority, attention only being needed to avoid planting too deeply beneath the surface of the water. Free exposure to light is also an essential condition, without which they make slow and unsatisfactory progress, a moderately low house being better adapted to their requirements than a lofty one. This, of course, particularly applies to the tropical forms which inhabit the lakes or rivers of the East and West Indies and Egypt, where they are exposed to the burning rays of a vertical sun. But during very hot weather in this country a little shade is found beneficial for the majority, differences being observable in the amount of direct sun heat the various forms will endure, some preferring a constantly slightly shaded position.

It is worthy of remark that the North American Nymphæas and others from similar climates also succeed admirably in the warm house, though they grow freely in tanks outside during the summer. Noticeable in this respect are *N. odorata* and its variety minor, both natives of North America, and resembling our much-admired hardy *N. alba* in form and colour, possessing considerable fragrance; the variety chiefly differing from the type in size. Both these were growing luxuriantly and flowering abundantly in the Oxford tropical tank, their charming white flowers being interspersed amongst the brighter shades of blue and rose. They are well worth including in any collection either for growing indoors or out. *N. nitida* was in similarly good condition; it is a Siberian form bearing white flowers, and like those already mentioned it can be grown in cool quarters out of doors. But by far the most interesting of these hardy Water Lilies is the diminutive and aptly named *N. pygmæa*, of which a leaf and two flowers are represented in the engraving (fig. 93). They are shown about the average size, but in a warm house, as it is grown at

Oxford, they frequently become larger. This species has been stated to be a native of Eastern Siberia, but it was brought to this country about the commencement of the present century from China, where it has long been in cultivation. Although the plant has thus been in English gardens for nearly eighty years it is still comparatively scarce, a fact which is the more to be regretted as it is so well adapted for growing in small tanks in cool houses. The flowers are pure white, and the leaves a rich green tint—a pretty contrast; and were it possible to obtain some forms with blue or rose-coloured flowers they would be very welcome additions. Those who have the means and opportunity of acting upon it would do well to consider the suggestion of Mr. F. W. Burbidge in his work on the "Improvement of Cultivated Plants." He remarks that "if *N. pygmaea* were fertilised with pollen from *N. rosea*, *N. caerulea*, or other species, a race of elegant miniature *Nymphaeas* might be the result," which is certainly within the bounds of probability, as some very satisfactory results have already been obtained in the genus by hybridising.

The really tropical and heat-loving Water Lilies now claim our attention, and these form the greater part of the collection under notice. One of the most handsome at the time of my visit was

Fig. 93.—*Nymphaea pygmaea*.

N. Devoniensis, a charming hybrid that originated at Chatsworth about thirty years ago. It was obtained by crossing *N. rubra* with *N. dentata* or *N. Lotus*, and is unquestionably a great improvement upon both parents. It bears very large rich crimson flowers which produced during the greater part of the year—a quality that is not possessed by many of the genus, while it is remarkable for the vigour of its growth. Altogether *N. Devoniensis* is one of the most attractive Water Lilies known. *N. Lotus* is the Egyptian White Lotus that grows in the River Nile, and of which *N. edulis*, *N. rubra*, *N. dentata* and others found in India are considered by some botanists as merely varieties. The typical form has flowers of moderate size, white tinged with pink. The tubers and seeds of *N. edulis* and some others are employed as food by the natives of the countries where they abound. Another of the Egyptian Lotuses is *N. caerulea* or *cyanea*, and this was flowering very freely, the colour being a very delicate blue tint. The flowers also possess a most agreeable fragrance—an additional recommendation of considerable value. *N. micrantha* is considered as a variety of that species; it is very pretty, but is deficient in colour and is chiefly remarkable for the buds borne on the leaves, which somewhat resemble the bulbils of *Liliums* or the plantlets produced on the fronds of some Ferns as they separate

from the parent and become new plants. *N. seutifolia* is similar to *N. caerulea*, its foliage being especially fine. The bright rose-coloured *N. rubra* has been incidentally referred to; and of all the other forms grown at Oxford I can only note one more—namely, *N. gigantea*, which represents the genus in Australia. This handsome species has very large rich blue flowers that are freely produced, and the plant is marked by its vigorous habit. It should be grown wherever sufficient space can be given to permit its unimpeded development.

While discussing the *Nymphaeas* it may be remarked that they are very variable, and much difficulty is experienced in defining species and varieties, and as a consequence considerable confusion exists in the names. Some valuable characters to aid in determining the different forms have been drawn from the seeds, flower buds, and air vessels in the stems and leaves.—L. CASTLE.

THE SEASON NEAR INVERNESS.

FROM what I read in the daily papers it would seem that the weather we have been having in these parts has been more or less general all over the United Kingdom. The heavy fall of snow which occurred here on the 17th ult., covering the ground in some places to a depth of 18 to 20 inches, has been followed by a general thaw, ushered in with strong gales from the south-west accompanied with heavy showers, and for the past three or four days the rain has been so persistent as to render all outdoor work almost impracticable.

This year we had an exceptionally warm summer, and in the beginning of August there was a grand display of what is known in these parts as "the merry dancers," otherwise the northern lights, which, instead of appearing as usually seen—like a bright halo in the heavens, on this occasion seemed more like the rolling waves of a prairie on fire, chasing one after another in rapid succession, continuing, as it were, flowing onward and onward from the north to the south. This was considered by most of those who have resided long in this district as sure indications of a severe winter. In 1860, when the "merry dancers" were seen, they appeared wonderfully bright but steady, and continuing every night for about five or six weeks. The thermometer then indicated, I am told, as low a temperature as $4\frac{1}{2}^{\circ}$ below zero, and it was the severest winter known. During the continuance of the snow this year the lowest temperature registered was, I think, 8° above zero, a difference of $12\frac{1}{2}^{\circ}$ from 1860; still, we had as sharp a frost as one would wish to feel.

There is no doubt that our climate is and has been undergoing great changes; and as evidencing this I would mention that in looking over some old family letters written from this glen nearly one hundred years since, the writer—a lady corresponding with her brother who was then in India—informs him "of the Peach tree in the open having yielded a wonderful crop that season, about one hundred having come to full perfection, many of them weighing from 6 to 7 ozs., and of the highest flavour." Now this was written from Sheughlie, a farmhouse situated at the extreme west end of our Loch Meiklie, which is about seven miles or thereabouts from Temple Pier on Loch Ness, and is considered about the coldest as it certainly is the bleakest-looking house in the whole glen. It is about 300 feet above the sea level. The same lady, writing in September, 1788, says, "The harvest has been a very good one in general, a good crop, and most of it already safely got home, but we in the braes of Urquhart are rather late by reason of a late seed corn we got amongst us. I must see to rectify this in future. Cows still give a great price—£4 10s., my father's price overhead. Corry (the neighbouring farmer to West) gives £5 and £6, but he has rather a better kind—in short, these are favourable circumstances in the highlands of Scotland. Butter and cheese also give an amazing price, and yet they are coming into the art of making much larger quantities than formerly."

Now, anyone attempting to grow Peaches in the open air would be regarded as nearly a lunatic! The frequent alternations of temperature to which we are subject, together with the very scant allowance of sunshine with which we are generally favoured, totally precludes all idea of growing any fruit except that of the hardiest kind. My gardener will have it that they were better people in those days than the present, and that is why they were blest with such good seasons. Whether this be the case or not—which, like any Scot, he would be ready to argue on—it is quite evident that our seasons are altering for the worse, for rarely do we hear now-a-days "of most of the crops being safely home by September." You will note the difference also in prices ruling in those days, £4 10s. being considered a great price for a cow, which now would fetch more than three times that sum. Unfortunately the price of butter is not mentioned; but if we may

judge from a comparison with that ruling at the present time—viz., 1s. 4d. to 1s. 6d. the pound, 6d. a pound would probably be about the figure.

Should, however, the above be of interest to your readers I offer it in the hope that someone may be able to deduce from his own observations the causes to which we are indebted for the apparent great difference in climate and temperature to that of former years.—W. W. ANDERSON.

ROOT-PRUNING AND TRAINING FRUIT TREES.

No. 2.

WHERE trees have been root-pruned or lifted a top-dressing of half-decayed material should be applied, as it prevents frost from penetrating deeply into the soil. If the work is performed early in the autumn it preserves a certain amount of heat about the roots and causes them to remain in a fresh condition until spring, when they will produce moderate growth and plenty of fruit buds.

Cultivators differ very much in their opinions respecting the pruning and training of fruit trees. One recommends cutting back the shoots to thoroughly ripened wood, another advocates leaving them their entire length. Under certain conditions both would be quite right in their practice. In heated structures it is easy to ripen shoots to their extremities; and if it be desired to cover a certain space as quickly as possible every shoot could be laid in its full length, except where they would be too thickly placed; and a house is soon furnished with vigorous young trees, or the branches of old trees can soon be made to occupy a space that it would take years to fill by so much cutting back. The extension of the branches must be limited to heated structures, except under most favourable conditions. The wet and sunless summer of last year, followed by a very severe winter, taught many having glass structures, and not possessing the means of heating them artificially, that the laying-in of branches their full length ends in disappointment. In such structures this year the case is very different. Trees under my charge that retained their foliage until the end of the present month of last year, are this season stripped of their leaves and the buds are quite prominent, more so than they were last February. In dealing with these trees last year I cut back closely and left the shoots much thicker than usual. This time they will most likely be thinned more, and those remaining left a greater length in pruning.

Last winter the shoots of Peach trees were killed, in many cases down to the old wood, but nevertheless they have this season made a moderate growth of fairly ripened shoots. Should the weather this winter prove as severe as last the branches are in a better condition to withstand it, and with judicious pruning and protection in spring I think we may be rewarded with a crop of fruit next year. Like the Peach, most of the trees are full of fruit buds, and at the same time have made a moderate and fairly ripened growth; so that where it is desirable to extend the area of the trees the shoots may be left longer than usual this season.

I will next write on the summer pruning of fruit trees.—ROBT. D. LONG.

CHARLWOOD HOUSE.

THIS, the residence of Norton Spark, Esq., is situated at Huyton, six miles from Liverpool. It is not extensive as far as the grounds are concerned, yet there are many glass houses suitable for the plants and fruit that occupy them. Orchids are the principal feature, and many of them were particularly fine at the time of my visit some months ago.

The stove contained a good specimen of *Croton variegatus*, well coloured, symmetrical in form, being 5 feet through and the same high. *Anthurium crystallinum* was also grand, having fine large leaves, and in excellent condition. *Marantas*, *Ixoras*, *Dipladenias*, and other stove plants were well represented. The roof was covered with *Bougainvillea glabra* and *Clerodendron Balfourianum* in flower, *Dendrobiums* and *Stanhoopes* being suspended from the roof in baskets, and were making luxuriant growth. Passing through a Peach house, in which the trees were healthy and bearing a good crop of fruit, we entered a vinery and noticed a good plant of *Thunia alba* growing very vigorously, also fine plants of *Dendrobium densiflorum* and *D. chrysotoxum*. Suspended in baskets underneath the shade of the Vines were *Dendrobium Wardianum* and *D. crassinode*, the foliage being of immense size, and the pseudobulbs strong; these Orchids evidently enjoyed their position in the shade, with no detriment to the Vines, which promised well for a good average crop of fruit. The next house in this range had been recently planted with *Roses*, and contained a miscellaneous collection of plants, amongst them being a fine specimen of *Aphelaxis macrantha purpurea* in flower.

Another house was partially occupied with Orchids; a large plant of *Zygopetalum Mackayi*, which had in the early spring about eighty flowers open upon it at one time, was especially noteworthy. The Cattleya house contained good plants of *C. Mendelii*, *C. Mossiae*, *C. gigas*, and *C. Skinneri*. The beautiful and rare *Cattleya amabilis* was in flower, with its delicate pink petals and lip of the richest crimson, also the following:—*Lælia cinnabarina*; *Trichopilia suavis*, which had six spikes carrying eighteen flowers; *Trichopilia crista*, a beautiful species bearing six large flowers; the free-flowering *Chysis Limminghii*, having four spikes and twenty blooms. This house also contained recently imported plants of the new *Lælia anceps alba*, which were starting vigorously into growth. A house was devoted to cool Orchids, and the first that drew our attention was a handsome plant of *Odontoglossum gloriosum*, having a four-branched inflorescence and about two hundred flowers. This is one of the finest specimens of its kind ever exhibited, and Mr. Sherwin was awarded a first-class cultural certificate for it at one of the Manchester shows. *Odontoglossum cirrhosum* was represented by several varieties in flower, one a fine dark variety and by far the finest I have ever seen; it had one spike and about twenty flowers open. Another had about thirty flowers. A third had one spike with eight branches or laterals, bearing fifty-two flowers; this was blooming for the first time under Mr. Sherwin's care, and is a very good variety. The beautiful *Odontoglossum Halli* with its large buff and brown flowers was represented by several plants. This I consider the finest of the dark-coloured section. One plant had two spikes and twenty-five large flowers; two others were coming into flower, one with a spike 4 feet long and the other 3 feet, the first having twenty flowers and the latter eleven. *Odontoglossum triumphans* had two spikes and sixteen flowers. Many other Orchids were represented, such as *Odontoglossum Alexandræ*, *O. Pescatorei*, *O. citrosum roseum*, and *O. pardinum*. *Disa grandiflora* was growing luxuriantly, also *Masdevallia Harryana* showing upwards of three dozen flower spikes.

An adjoining house was partially devoted to Ferns and partially to Orchids, the former filling the back portion of the house and planted upon neatly arranged rockwork, the front being devoted to the Orchids, and many were suspended from the roof in baskets. Two plants of *Dendrobium Devonianum* were in flower, having about a hundred flowers each; *D. Picardi latifolium* had fifty flowers, and *D. Freemani* thirty fine flowers; the lovely little *D. pulchellum* was also well bloomed. On the front stage we noticed a quantity of *Odontoglossum vexillarium*; some of them imported last July were showing flower freely. This lovely *Odontoglossum* is a free grower in a little warmth, and flowers profusely. *Odontoglossum Roezlii*, *Cœlogyne barbata*, and *Cymbidium Lowianum* were doing equally well. *Oncidium ornithorhynchum* had ten good leads, and produced twenty good spikes last autumn. *Oncidium incurvum* had twenty breaks, and the rare *Zygopetalum Gautieri* was doing well.

The East Indian house contained a good specimen of *Dendrobium Dalhousianum* bearing fifty flowers. This is a lovely species, and doubtless highly prized by those who have fine plants, yet the flowers are of very short duration. The old *Oncidium sphacelatum* had ten large spikes of flowers. *Cypripedium lævigatum* had six flowers. The plants of *Phalænopsis Schilleriana* were grand in pots. *Grammatophyllum Ellisii* was growing well; *Saccolabium Blumei majus* was also fine. The conservatory is situated at the end of this range, and contained an assortment of the usual flowering plants intermixed with good plants of *Dendrobium nobile* and its varieties, of which there are two grand forms, one having the petals and sepals all white, with a much darker spot on the lip than *nobile*. The other is much larger in the flower, and the pink markings on the sepals and petals, as well as the crimson spot of the lip, being more vivid than in the species.

I have only enumerated a few of the many Orchids which are comprised in this collection. Mr. Sherwin has a liberal employer, who takes great delight in Orchids, and all appear to be thriving well under the treatment they receive.—W. BARDNEY.

LOASAS.—Numerous as are our winter-flowering plants there are still some which are rarely seen, although worthy of attention. This is the case with the above genus, the species of which are admitted to possess both curious and attractive properties, as well as some that are very objectionable. The leaves and stems often bear numerous glands yielding poison far more irritating than our Stinging Nettle, consequently the cultivator should be careful to avoid touching them with his unprotected hands. All the species are easily raised from seed sown in the early spring in a mild bottom heat, and when the plants are large enough they

may be potted several together in light, sandy, rich compost in small pots. While growing they like a moist heat. They are of climbing habit, and are well suited for training up pillars in conservatories. After being hardened off a cold pit is adapted to their requirements, giving attention in dry weather, as they are liable to be attacked by the red spider. When in full bloom during the late autumn and winter they are very beautiful. The species I have grown are *Loasa lateritia*, beautiful and curious; *L. Herberti*, and *L. aurantiaca*, a telling plant in the greenhouse or conservatory during winter.—ADANSON.

DRACÆNAS FOR TABLE DECORATION.

AMONG the numerous plants now in demand for table decoration few excel the narrow-leaved *Dracenas* in gracefulness and general utility. They are easily and quickly grown to a suitable

size, and they endure the dry atmosphere of rooms much better than the majority of plants employed for such purposes, except some Palms. The elegance of their habit also renders them pre-eminently fitted for occupying the centres of tables, as their foliage is not too dense or too obstructive—disadvantages which appertain to the broad-leaved forms in the same genus, and to other plants with large leaves. Such qualities as those enumerated are sufficient to account for the partiality with which they are regarded by all who have employed them in decoration of the kind under consideration, and indeed they cannot be too highly recommended to the attention of those who have only the means to grow the most useful plants.

The numerous handsome hybrids that were raised by Mr. Bause and sent out by Mr. John Wills include several of the best narrow-leaved forms in cultivation. One of these, *D. jucunda*, the result of a cross between *D. limbata* and *D. concinna*, is represented in

Fig. 94.—*DRACENA JUCUNDA*.

the woodcut, fig. 94, which has been supplied by the General Horticultural Company. This, as the engraving shows, is an effective and graceful form, erect in habit, with narrow leaves slightly drooping towards their apex. The colour of the leaves is a bronzy green margined with bright crimson. It is remarkably free of growth, and altogether a really useful and pretty table plant. Another similarly elegant plant is *D. Ernesti*, obtained by crossing *D. concinna* with *D. terminalis*; it is rather more compact in habit than the one first described, the leaves being more arched. The colour is, however, similar, the margin being a somewhat deeper tint of crimson. *D. Sidneyi* is a third form of considerable elegance. One of its parents was the same as that of *D. Ernesti*—namely, *D. concinna*, the other was *D. Regina*; but it is very distinct, and especially noteworthy for the early stage in which the foliage become fully coloured, a quality that particularly adapts it for table decoration. The leaves are deep green,

with a purple midrib and a bright rosy margin. *D. aurantiaca*, a slender-growing and attractive form, has the same parentage as the one described last. The leaves are longer than the others, narrow, green, with a clearly defined orange-coloured margin, the young leaves being of a similar tint. *D. superba* is equally worthy of attention, for it is graceful in habit and bright in colour, the arching green leaves being edged and streaked with crimson. These five *Dracenas* would constitute a valuable collection wherever table plants are in demand.—L. C.

SOIL FOR ASPARAGUS.—If Mr. Nunns (see page 503) had dug into the beds the same quantity of Beech or Oak leaves that he did of dung I think he would have done the soil much more good. The leaves are best gathered dry in the autumn, and dug plentifully and deeply into the ground twelve months previous to plant-

ing. Asparagus does not like what is called here (Gloucestershire) a clung heavy soil. It is a good plan to mulch the beds with leaves or the remains of old Mushroom beds. Wood ashes mixed with salt form an excellent application on heavy soils.—A. TAYLOR, *Langford House*.

FOR several years past the display of CHRYSANTHEMUMS AT GARBRAND HALL, the residence of Mrs. Torr at Ewell, has been rendered by Mr. Child's skill and taste unquestionably one of the most effective in the country. This season it is as fine as usual, the great number and excellent colour of the blooms compensating for their somewhat smaller size generally, although there are examples of several standard varieties quite up to exhibition form. As was stated last year the plants are arranged in a span-roof Peach house 100 feet in length, and are trained to an improvised trellis on each side of the central path so as to form an avenue of foliage and flowers, arches crossing the path at intervals of about a dozen feet. The colours are tastefully intermingled, and as viewed from one end of the house the effect is charming. Mr. Child states that he usually has his Chrysanthemums in good condition for about two months.

— Mr. W. ROBERTS sends us the following note on PASSIFLORA CÆRULEA in Cornwall:—"Visitors to Penzance are often surprised to see this beautiful deciduous twiner bearing its fruits in midwinter. There are now several specimens fruiting well around here, but the one trained against a house in Coulson's Terrace is decidedly the most beautiful of all. At such a dull season it is quite refreshing to see the plant still covered with leaves and bearing numerous Orange-like fruits. There is another not far from the one mentioned above, in a much more exposed situation, only a few feet from the sea; it is quite destitute of its foliage, but has still a few fruits."

— THE same correspondent writes in reference to BROCCOLI IN CORNWALL:—"The Broccoli crops here are looking well, and there is every prospect of their realising a good price. Not only are the plants robust, but the greatest quantity of seed has been harvested that has ever been known to be obtained in one season. Last year one market grower only obtained half a pound of seed from half an acre of plants."

— CHRISTMAS CARDS may be thought to be outside the scope of this Journal, but a packet which we have received from Messrs. Eyre & Spottiswoode, the Queen's printers, teach us that there is a close connection between them and gardening. The illustrations, of which these cards supply a great variety, abound so much in beautiful representations of flowers, and are executed in such a superior style, that they excel in fidelity and in art the illustrations with which some professed gardening publications are adorned. Not less faithful than the floral are the natural history subjects, and the figure representations are equally works of art.

— WE have received the schedule of the BALLARAT HORTICULTURAL SOCIETY, which gives particulars of the classes, prizes, and regulations for their three annual exhibitions. It is curious to note the dates of the shows. For instance, the one fixed for October the 15th of the present year was the spring bulb show; the ordinary spring show was held on November the 18th and 19th; and the autumn show is announced for March the 17th and 18th, 1881. The prizes are generally of small amount, but the classes are very numerous. The chief display of fruit and vegetables is

at the March show, at which there is provision for all the chief kinds cultivated in England. One regulation deserves notice, and might be advantageously adopted in this country—namely, "No protest will be entertained unless accompanied with a deposit of 5s. which sum shall be forfeited if the protest is found to be frivolous."

— A DINNER, complimentary to CHARLES M. HOVEY, Esq., the eminent American horticulturist and one of the founders of the Massachusetts Horticultural Society, was given on October 30th, in honour of his seventieth birthday. Over sixty gentlemen were present, including Col. Marshall P. Wilder, who is eighty-two years of age.

— WE have received Parts 9 and 10 of LETTS' POPULAR ATLAS, which are marked by the same care and taste in production that we have referred to previously when noting the other parts of this useful work. Part 9 contains clear and well-executed maps of the West Indies, the islands differently coloured to indicate the countries to which they belong, with statistical maps of Italy and North America, the latter accompanied by an inset map of the British Islands drawn to the same scale and showing their relative proportions. Part 10 has an elaborate statistical map of Canada, showing the mineralogical characteristics of the different districts, the range of Wheat cultivation, and many other particulars of interest; a clear map of Egypt, and a similarly excellent delineation of Spain and Portugal, in which the districts devoted to the production of wines are marked in different colours.

— WE recently referred to some of Mr. H. Cannell's beautiful Salvias, particularly noting *S. Betheli*, *S. splendens* Bruanti, and *S. Pitcheri*; but there is another which we have also received from Swanley that is deserving of attention—namely, *SALVIA HOVEYI*. This, though not so brilliant in colour as the others, has large flowers of a rich purple tint, and bearing a peculiar satiny gloss that is very striking. It forms a good companion for those named above, and may be advantageously included in any collection of winter-flowering plants. It commemorates the name of the well-known American horticulturist, Mr. Hovey of Boston.

— WRITING to us on COOKING MOORE'S VEGETABLE MARROW, our correspondent "G. O. S." observes:—"Those who desire to have this vegetable in perfection at table should boil it whole, its delicate flavour is then preserved; if cut into slices and boiled it merely produces broth which is thrown away, and the insipid refuse is placed on the table."

— REFERRING to Carter's JERSEY LILY TURNIP, a correspondent states that it is superior to the Snowball. From seed sown in August he had roots ready for use in seven weeks afterwards, and "at the present time it surpasses all others in the garden."

— MESSRS. W. WILLIAMS & Co., 55, Moorgate Street, E.C., have sent us samples of their BOTANICAL DRYING ALBUMS, which appear to be admirably adapted for drying specimens of plants. The paper is of good quality, and is said to be specially prepared to obviate as much as possible the destruction of colours in flowers usually attendant on the drying process. There are two sizes, one 11½ inches by 8½, and the other 11½ by 17¼. The albums are neatly bound in cloth, constituting desirable acquisitions for every amateur botanist. The drying paper is sold separately at 2s. 6d. per quire.

— A CORRESPONDENT "A. J. B.," referring to a supposed difficulty, as expressed by Mr. Taylor on page 487, of obtaining trained trees of the WINESOUR PLUM, states that he wrote to Messrs. Veitch, and they sent him some good healthy trained trees with well-ripened wood.

— PART IV. of the re-issue of PAXTON'S FLOWER GARDEN contains two coloured plates; one a very fair representation of the beautiful Orchid *Odontoglossum vexillarium*, and the other of *Pæonia Moutan atro-sanguinea*, rather too dull in colour, together with a continuation of the "Gleanings and Original Memoranda" which appeared in the first edition.

— THE following note respecting the ANCIENT SOCIETY OF YORK FLORISTS' AUTUMN SHOW is abridged from the *Yorkshire Gazette*.—When the Ancient Society of York Florists was first instituted is a moot point, since the earlier records of its existence have been lost; but that its age is very great there can be no doubt, since an account of one of its meetings, in which it is termed "Ancient," is to be found in a file in the *York Courant* for 1760. The Society had had a very long career of usefulness in a quiet and unpretentious manner, and good autumn shows were held. Some months ago it was determined that the autumn Exhibition of this year should possess a new feature by embracing a display of Chrysanthemums, which should hold the most prominent place, whilst Camellias, Ferns, Hyacinths, and fruits and vegetables should be ranked as secondary exhibits. The Show was held in the central and large halls of the Exhibition buildings, and it took place under the patronage of the Archbishop of York, the President of the Society, and other influential patrons. In every respect the Exhibition was successful. The principal part of the Show was in the large hall, on each side of which were eight large pyramidal groups of various colours of Chrysanthemum, interspersed with other winter plants and flowers, and the sides of the hall were devoted exclusively to the Chrysanthemums for competition, and also for plants and fruits. The array of Chrysanthemums was most extensive, and nothing had previously been seen in York approaching to it in numbers, whilst in quality the specimens staged were all of unexceptionable merit. Ald. Melrose sent some plants from his conservatory, and Messrs. Backhouse & Sons displayed near to the entrance a splendid group of Coniferae. The Judges were Mr. Clayton, gardener to Mr. J. Fielden, Grimston Park; and Mr. Link, gardener to Lord Herries, Everingham Park; Referee, Mr. J. Fielden, gardener to the Yorkshire Philosophical Society. The following were the principal prizetakers—Mr. J. H. Hingston, North Riding Asylum; Messrs. Lazenby & Son; Mr. Key, Bootham; Mr. I. Smith, Layerthorpe; Mr. H. Newton, Grove Lodge; Miss Steward, Bishopthorpe; Capt. Darnell, and Messrs. Noble and Ridsdale.

— THE interesting notes on the HARDINESS OF NEW ZEALAND PLANTS, read by Mr. W. Gorrie before the Edinburgh Botanical Society in January and July of the present year, have been reprinted from the Transactions of that Society, and a copy is now before us. The notes take the form of a detailed description of the effects produced on a number of New Zealand plants at Rait Lodge, Edinburgh, by the winters from 1878 to 1880. Not only is the respective hardiness of the plants indicated, but much useful and interesting information is embodied relative to their decorative value, their products, or their peculiarities. Among the plants that escaped injury were *Fuchsia procumbens*, on a rockery; *Discaria Toumatou*; *Olcaria Haastii*; *Veronica Traversii*, *V. pinquifolia*; *Chrysobactron Hookeri*, and *Aciphylla Colensoi*. Those injured but not killed constituted the majority, the principal being *Plagianthus betulinus*, *P. divaricatus*, *Edwardsia pulchella*, *Corokia Cotoneaster*, *Phormium tenax*, *Griselinia littoralis*, and *Leptospermum scoparium*. The following were killed—*Rubus australis* and var. *eissoides*, *Veronica salicifolia*, *V. Hulkeana*, *Arundo conspicua*, and *Libertia grandiflora major*.

— AT the ordinary meeting of THE METEOROLOGICAL SOCIETY to be held at 25, Great George Street, Westminster, on the 15th inst., at 7 P.M., the following papers will be read:—

"Report on the Phenological Observations for 1880," by the Rev. T. A. Preston, M.A., F.M.S.; "On the Variations of Relative Humidity and Thermometric Dryness of the Air, with Changes of Barometric Pressure at the Kew Observatory," by G. M. Whipple, B.Sc., F.R.A.S., F.M.S.; "On the Relative Frequency of Given Heights of the Barometer Readings at the Kew Observatory during the Ten Years, 1870-79" by G. M. Whipple, B.Sc., F.R.A.S., F.M.S. As the list of Officers and Council for the year 1881 will be prepared at the next Council Meeting, it is requested that those Fellows who wish to suggest names for the new Council will send them in before the 15th inst.

— OUR correspondent "W. J. M." refers to PELARGONIUM MARGARET PONTON as follows:—"Of all the Zonals for winter blooming I know of none to compare with Bertrand's Margaret Ponton. Though generally classed as salmon-coloured the eye is more of a bright scarlet pink; there is a large pure white margin, and when grown in a comparatively small pot and with rich sandy soil, and given an occasional supply of liquid manure, it will bloom profusely during the winter months. It has been blooming with me since July, and promises to continue for months to come, with only ordinary care."

— NEW ROSES.—The Rose referred to by "J. B." on page 512 as "Madame Levette," is no doubt Madame Etienne Levet, a Hybrid Tea sent out by the English Rose-growers in the spring of 1879. The following new Roses may, I think, be safely added to your list of good varieties—viz., Claude Bernard, Jules Chrétien, Louis Doré, Pierre Carot, Souvenir de Madame Robert, Rosy Morn, Lord Beaconsfield, Paul Jamain, Souvenir de Victor Verdier, Egeria, Madame Eugène Verdier, Catherine Soupert; and Bennett's Pedigree Seedling Roses, notably Beauty of Stapleford, Hon. George Bancroft, and Viscountess Falmouth.—WM. WALTERS, *Burton-on-Trent*.

PORTRAITS OF NEW AND NOTABLE PLANTS.

DRACONTIUM CARDERI.—The genus *Dracontium*, as restricted by Engler in his recent Monograph of the Aroidae, includes the wonderful *Godwinia Gigas* of Nicaragua, and consists of this and two other species, natives of N. Brazil and Guiana; to these must be added *D. Carderi*, which extends the geographical range of the genus to the United States of Columbia, and which differs from its congeners in the smooth petiole and very long peduncle. It was discovered by the traveller whose name it bears, and was imported by Mr. Bull, who flowered it at his establishment in Chelsea in April, 1879.—(*Bot. Mag.*, t. 6523.)

HIBISCUS SCHIZOPETALUS.—"This singular and beautiful plant has attracted much attention, on account both of its horticultural and botanical interest; differing as it does from all other species in the remarkable character of its petals, and yet presenting so many points of resemblance to a world-wide garden favourite whose native country is unknown (the *H. rosa sinensis*), as to have suggested its specific identity with that plant. The differences, however, between this and *H. rosa sinensis* are a great deal too many and too important to render the idea of this being a sport or variety of that plant tenable. They are, firstly, the petals, which, however, might have originated as a sport; then the pendulous flower, the suppression of the epicalyx, the longer tubular calyx with obtuse lobes; above all, the long fruit with small smooth seeds. For the discovery of this fine plant we are indebted to our indefatigable correspondent, Dr. Kirk, H.B.M. Consul at Zanzibar, who found it first in 1874 on the coast hills at Mombasa, in lat. 4° S.; in 1877 at Kilwa, in 7° 40' S.; and, lastly, at Lindi, in 10° S. It grows both in dry rocky slopes and in damp mountain glens, in dense shade, amongst Bignonias, Balsams, and Ferns."—(*Ibid.*, t. 6524.)

CRINUM PURPURASCENS.—"This is a very distinct *Crinum* of the star-flowered set from West Tropical Africa, remarkable for its dwarf slender habit and very numerous spreading narrow undulated leaves. Its alliance is with the Himalayan *C. amœnum* and *pratense*, and the New World *C. americanum* and *erubescens*. It was introduced in the time of Dean Herbert, and is carefully described in his classical work on the Amaryllidaceae, but has never been previously figured. It grows at a low level by the side of streams about Fernando Po and in Old Calabar, and,

of course, requires stove heat for its successful cultivation."—(*Ibid.*, t. 6525.)

SCABIOSA PTEROCEPHALA.—"A densely-tufted perennial, forming large low cushions, perfectly hardy, and when in flower very ornamental. It has been long cultivated in Kew in the open border of the herbaceous ground. It is a native of the mountains of Greece, growing in dry rocky places at elevations of 3000 to 6000 feet, and extends from the Ionian Islands (Mount Nero in Cephalonia) to Mount Athos in Macedonia, and Parnassus in Attica. At Kew it flowers in July and August."—(*Ibid.*, t. 6526.)

CALOCHORTUS PULCHELLUS.—"The Calochorti, of which between twenty and thirty species are now known, belong exclusively to California, British Columbia, the Rocky Mountains, and Mexico, and one and all seem to require greater heat than an English summer gives them to mature their bulbs properly. The present species and *C. albus* are well marked from all the others by their more robust habit and numerous large drooping globose flowers, which never expand fully and are much less fugitive than in the more brilliantly coloured *C. venustus* and its neighbours. Calochortus and Cyclobothra slide into one another so gradually that it is not worth keeping them up as distinct genera. *C. pulchellus* was one of those introduced by Douglas about 1830, when travelling for the Royal Horticultural Society, and was originally described and figured by Mr. Bentham half a century ago."—(*Ibid.*, t. 6527.)

PEARS IN CHESHIRE.

"WILTSHIRE RECTOR" asks for the experience of amateurs respecting Pears grown as pyramids. It takes many years to form any experience that is worth having. In the first place, the trees are several years before they begin to bear, and when they are in a bearing condition you must have several crops before you can form a fair opinion concerning the quality of the fruit. I have found that no fruit varies so much from year to year. Some few varieties, it is true, appear to be pretty constant—Marie Louise and Winter Nelis for example. Both of them I grow against a wall. The former is a shy bearer as a standard, and the fruit is of course smaller, but the quality is good. I have not tried it as a pyramid, but it is a straggling grower and requires careful pruning, so I prefer to grow it, if away from the wall, as a standard. Winter Nelis cankers as a pyramid, and I have been obliged to graft it with another variety. Other varieties, however, vary much with the season, being in one year so bad that you feel inclined to root them up, and in another good enough to win a reprieve.

I have not yet discovered many varieties which do thoroughly well without a wall to help them. My experience, however, is at the service of "WILTSHIRE RECTOR," though I fear it will not be of much use to him, since my soil and climate must differ considerably from his. Jargonelle, for instance, which he describes as the Gloire de Dijon among Pears, is anything but satisfactory here. As a pyramid it cankers badly, and the fruit is nothing to speak of. Grown against a wall, as "WILTSHIRE RECTOR" grows it, it would no doubt be much improved, but I devote all my wall space to winter Pears of higher quality. I should not place Jargonelle in the first dozen, perhaps not in the first twenty. Williams' Bon Chrétien I grow as a standard. It is a healthy grower and good bearer; as a fruit I do not like it, but it comes in at a useful time. Seckle as a pyramid would be small and probably unhealthy; grown against a wall it is of good size and very delicious: so very distinct as to be almost indispensable in a collection. Beurré Diel grows well here as standard or pyramid, but the fruit is apt to crack and does not always ripen satisfactorily. When well grown and ripened this is a fine-flavoured juicy Pear. Louise Bonne of Jersey with me grows excellently, and is a thoroughly good bearer as a pyramid; indeed, if the fruit were a little better I should describe it as thoroughly satisfactory. The fruit is moderately good, but is not of the highest class. I have found it answer to gather this Pear before it is quite ripe; if left too long on the tree the flesh is apt to become mealy.

Now to speak of some others not mentioned by "WILTSHIRE RECTOR." Has he tried Doyenné du Comice, Comte de Lamy, Thompson's, Beurré d'Arenberg, Glou Morceau, Beurré Superfin, and Beurré d'Amanlis? These all do well with me as pyramids or standards, and the fruit is very superior. Glou Morceau, oddly enough, does better here in most years as a pyramid than against a south-east wall. It is not so large of course, but ripens better, and is altogether a better Pear. Doyenné du Comice is a very fine Pear and healthy grower; I have not had it long enough to say if it is a good bearer, but am told that it requires time. I have two different trees both named Beurré d'Arenberg, but very different both as to growth and fruit. One is a slender grower,

but quite healthy against a wall, bears large fruit of first-rate quality, and this year is quite my best Pear; the other, a strong and healthy grower, does well as a pyramid, is a good cropper, and the fruit is very useful. I think this is the true Beurré d'Arenberg. Beurré d'Amanlis is usually good, but when the fruit is extra large it is apt to be coarse. Maréchal de Cour I have discarded; the fruit was not good enough. Bergamotte Esperen does well with me against a wall, but I rank it inferior to Winter Nelis and Joséphine de Malines, which ripen with it. Winter Nelis is my type of a good wall Pear; it is first-rate in every respect. Beurré Bosc I have tried several seasons, and have at last condemned it as not good enough. Brockworth Park has fruited this year for the first time against a south-east wall. It is something like a Louise Bonne of Jersey, but inferior. It, too, is condemned. I am trying many other varieties, but as yet have no further experience to offer, except that I have been obliged to do away with Knight's Monarch as a pyramid. I never could ripen the fruit; it constantly fell off before its time and shrivelled.

As to Apples, if "WILTSHIRE RECTOR" wants a really first-rate kitchen and dessert variety let me strongly recommend Maltster. As a dessert Apple it is A1, while it is also very good for baking. It should be allowed to hang on the tree as long as it will, and is then scarcely inferior to a Newtown Pippin. I have found the Calville Blanche on the French Paradise stock quite worthy of a place on the best wall. It is a sure cropper, and the fruit very fine.—CHESHIRE RECTOR.

NOTES ON BIRDS—TRAPPING BULLFINCHES.

"WHEN a man has a hobby he is apt to ride it a little too hardily." So wrote "A PARSON" in a neighbouring county on page 310, April 22nd. This is no doubt true in many cases; and I would not venture to ride mine again so soon over the pages of the Journal—although I am pleased to find I have interested at least two readers—were it not for the suggestion of Mr. Harrison Weir on page 460. It is not my wish or intention to carry on a paper war over so trifling a matter as the bill of the blackbird with so eminent a naturalist, whom all must admire who have seen his excellent life-like drawings of birds and animals; still I find it hard to give up honest fixed ideas, and must retain my opinion, from observation on hundreds of specimens I have handled, that the variation of colour of bill and plumage in this locality is due as a rule to age. Sometimes we have exceptions in colour, as I have a pied specimen nearly half white, and I have read of white ones. A pure white house sparrow was reared here a few years ago; a cream-coloured starling was also reared in this neighbourhood.

Mr. Harrison Weir's communication opens up so many subjects of interest that I hardly know which to reply to without going through the whole, which I shall not be able to do on this occasion, but must confine my remarks to the bullfinch. He asks, How are they best trapped? As no one has replied to it, and I have ventured on two occasions in the Journal to advise catching, I feel it a duty to give my experience, as theory without practice is not worth much. The statement made on page 436 that bullfinches are unusually plentiful this autumn is being borne out by numbers which I was hardly aware of, as acting myself upon the advice then given I commenced catching those which were visiting me, and during the last three weeks I have cleared my garden of exactly a score. As we are so accustomed to the annual grumbling and writing in the Journal about fruit buds being destroyed in the winter by bullfinches, I believe it will prevent most of it if gardeners will adopt the means I have, and will probably save tons of the best fruit, as bullfinches are no mean judges of the best Plums, my Green Gage, Golden Drop, and Damson buds always being preferred to the somewhat insipid Orleans. Those readers of the Journal who have the number for April 29th, 1880, page 336, will find that I stated I had only been troubled with one bird during the last two winters. As the spring advanced the sprays on my Gooseberry bushes referred to, which had been attacked, stood out bold and clear with scarcely a leaf on, like "churchwarden" pipe stems, and looked very conspicuous, as the foliage was developed on the other part of the bushes.

I find the best way to trap bullfinches is to procure a caged bird. I borrowed one for a start this year, also what is known as a trap-cage, putting the tame bird in the lower part, placing a bunch of Blackberries or Privet berries in the top part; hang the cage against a wall or tree out of the reach of cats. I have reserved a stock of bunches of Blackberries by inserting their stems in water Grape-fashion for a succession of food for bait (see page 336 above referred to). I have also caught scores, if

not hundreds, on birdlime, but this injures their plumage and is somewhat troublesome, especially to anyone not accustomed to handle it. I have also caught them in a bat fowling net at night out of thick hedges. I find a trap cage or cages best, for bullfinches generally go in small parties, and I have taken two out at once from two separate cages, while others waited round and were caught afterwards.

The well-known and easily imitated call of the bullfinch at this season of this year appears to have a greater attraction—for what reason I cannot say—than at any other period; there is also a great difference in individual call birds. The best should be

selected. When fresh caught bullfinches are best placed in a low kind of box cage about 6 inches deep, with wires only on one side. Such cage may be easily made out of a soap box from the grocers, giving them a good supply of canary and hemp seed and water. If they refuse to eat the seed, which sometimes happens, give a few Blackberries or such other food as they feed on at the time; the seed of the Dock is always a favourite dish in the winter, and the probability is in a day or two they will take to the seed, which should be strewed over the bottom of the cage. In a few days they may be placed in store cages in an aviary or sold. There is always a demand for them as pets, although their

Fig. 95.—HERO OF LOCKINGE MELON.

natural song is not pleasing; they soon become very familiar, even more so than a life-long-caged canary. I well remember when a boy hearing the first over my head in a Larch tree, and how I longed to have the bright-breasted fellow for my own; since then how many have been taken to Birmingham during the cattle show weeks and sold I know not, but I generally used to take enough to clear my day's expenses, and that is what I wish to impress upon the minds of the readers of the Journal. Instead of grumbling at the depredations of the birds and shooting them, and the fruit trees at the same time, catch them and turn them into cash on the score of economy and humanity.

I may have some remarks to make upon the tit family at some future time, and should like to hear the opinion of other bee-

keepers respecting the bee-killing propensity of these birds. I am of opinion that Mr. Harrison Weir is mistaken when he says they have "eaten all my bees," unless a very limited stock.—
JAMES HYAM, *Worcestershire.*

HERO OF LOCKINGE MELON.

THIS fine new Melon was raised by Mr. Atkins, gardener to Col. Loyd-Lindsay, M.P., Lockinge Park, Wantage. The raiser informs us that he obtained this Melon by first crossing Colston Basset with Read's Scarlet-flesh, then crossing the variety so produced with Gilbert's Victory of Bath. Mr. Atkins, in a letter before us, describes the Hero of Lockinge as of sturdy habit, a

good setter, the fruit being very deep in the flesh, which is of a whitish colour, melting, and of rich quality. He intends growing it largely next year. Externally the fruit is very handsome, being bright golden yellow, distinctly and chastely netted with pure white. It is of medium size, globular and symmetrical, and was awarded a first-class certificate at the Reading Horticultural Show in August last; it also received the first prize in its class, and the high encomiums of the Judges. Messrs. Sutton & Sons have received the stock of this Melon for distribution, and we are indebted to them for the accompanying accurate representation of the fruit that was certificated.

HARDY FRUIT GARDEN.

THE Apple and other orchard trees should now have whatever attention they may require in pruning and thinning-out superfluous branches, spurs, and dead wood. The thinning of the heads will require to be done with considerable care, as to take out a quantity of wood at once would only cause a number of shoots to be produced in the following season, and these will crowd the head with much useless wood. Confine the thinning to cutting out growths that cross each other, and where they are crowded or weak. Moss or lichen may be removed from the stems and branches of aged trees by scraping, and afterwards dressing with strong limewash, or with brine; add 1 lb. of soft soap to every gallon of brine, and apply it with a painter's brush. The brine is preferable to limewash, which is unsightly, and if used should have the addition of a portion of soot. Gooseberries and Currants are too often neglected in pruning at this season on account of the danger of the destruction of the buds by birds in severe weather. In pruning it must be borne in mind that the Gooseberry bears chiefly on the young wood of the present year's growth, and on spurs; where the young wood has been shortened back the growths should be moderately thinned, those not required spurred-in, and the long shoots shortened so as to form a symmetrical bush. Pendulous varieties may be encouraged to make more erect growth by keeping a clear stem, and shortening the points of the lower shoots so as to keep the fruit when in bearing clear of the ground. Red and White Currants may be spurred-in to the main branches, those not being more numerous than requisite to form a well-shaped bush, keeping the centre open, so as to admit light and air to the fruit. Black Currants give the finest fruit from the young wood, which should be encouraged by thinning-out the old growths, shortening the upper branches where required. After pruning the bushes and clearing the ground a dressing of manure must be spread over the whole surface (unless the bushes grow too luxuriantly) and be lightly forked-in, except in the case of young trees, which will admit of cropping between, when the ground may be worked deeper. Where the roots are mutilated annually they are driven downwards, resulting in a superabundance of half-ripened strong shoots, producing little if any fruit. The Raspberry is one of the most useful of small fruits, and prefers a moist soil, but free from stagnant water. Ground intended for new plantations should be deeply trenched and well manured. The mode of training is variable, some using stakes of 4 to 5 feet above ground, and cutting back the canes to the same height; others tie the selected canes, dispensing with stakes. Some growers tie the ends of one set of canes to those of the next stool in the line, so as to form an arch of the bearing canes; and others, again, merely thin-out and shorten the canes, leaving them loose, with the exception of surrounding the plantation with a line of tarred string or wire supported by stakes to maintain the outside canes in position; and some adopt the best plan of all—viz., securing the canes to light rails or wires formed similar to espaliers, and about 5 feet in height. As soon as the pruning is completed manure the ground and have it dug or pointed over. Among the varieties Red Antwerp, Carter's Prolific, and Fastolf are the best. If a yellow be wanted Yellow Antwerp is good. Autumn-fruiting Raspberries are a most useful addition to late culinary fruits. October Red,

Belle de Fontenay (red), and October Yellow are good free-bearing varieties. They may now be cut down close to the ground, having previously taken up any straggling canes if any are needed for planting, afterwards giving a good dressing of half-decomposed manure, merely pointing it in. The canes should be thinned in early summer, so as to induce a strong growth in those retained and insure an autumn crop, which is borne on the young growth of the current season.

KITCHEN GARDEN.

Forcing Department.—Where large supplies of French Beans are required a suitable structure should be devoted solely to them, in which the seeds can be sown and plants grown in beds under conditions that will afford much more satisfactory results than from pots. A bed of 10 to 12 inches depth should be provided of rich light soil, sowing the seed in rows about 18 inches apart. The front of Pine beds may be utilised in this way for single rows, sunshine having free access, making a border about a foot wide and 10 inches deep, which will yield satisfactorily if properly attended to with water, mixing a little guano with it occasionally, or some other stimulant. In accordance with the demand continue successional crops of Asparagus, Seakale, and Rhubarb, and prepare fermenting materials for advancing succeeding supplies. Make up beds of leaves and litter in pits and frames for Potatoes, Carrots, and Radishes. The Carrot and Radish seed should be sown in alternate rows in shallow drills about 4 inches apart, using fine rich soil. Early Nantes and French Forcing are suitable varieties of Carrots. As soon as the seeds vegetate, especially those of Radish, ventilation must be freely attended to. Insert sets of Potatoes in leaf soil in boxes, placing them in a house where there is a moderate temperature preparatory to planting in the beds. Myatt's Prolific and Veitch's Ashleaf are suitable varieties. Rhubarb and Seakale in Mushroom houses must be abundantly watered when necessary. Asparagus in bearing should be liberally ventilated when external conditions are favourable. Admit air freely to Lettuces, Endive, and Cauliflowers in mild weather; but during severe weather they will not suffer any damage if the coverings are left on for several days. Heated pits containing Lettuce and Endive require regular attention in ventilation.

FRUIT HOUSES.

Pines.—If a supply of ripe fruit be desired in May and June, and a sufficient number of plants are not showing fruit to meet such requirements, it will be necessary to take some of the plants from those which were started last March and are now in a state of rest. Select the best developed plants of the Queen, Enville, and Providence varieties, such as appear most likely to produce fruit when subjected to a higher temperature. Do not, however, start more plants than are needed; they will throw the fruit up more readily and be much stronger if started a month or six weeks hence. If the plants cannot be placed in a compartment to themselves a light position in the house where the fruit is swelling off should be given them, continuing the routine as before advised.

Peaches and Nectarines.—Fire heat will now be necessary in the earliest house if all the preparations for forcing have been made; but the night temperature must not exceed 40° to 45°, and 50° in the daytime artificially until the blossom is well advanced, when the heat may be gradually increased to 45°, not exceeding 50° at night, and 55° in the daytime from fire heat, ventilating freely above that temperature. The trees may be syringed daily until the anthers show, then confine the damping to surfaces in the house. A little air may be admitted at night to prevent a close vitiated atmosphere, which is unfavourable to the proper fertilisation of the blossoms. See that the borders inside do not become too dry. An excessively dry condition of the soil may not cause the buds to be cast at once, but they may drop later instead of swelling.

Cherry House.—With a view to obtain ripe Cherries at the end of April, or from early May onwards, the house must now be closed. If the border be deficient of moisture a thorough soaking of water should be given. Syringe the trees and surfaces in the house early on fine afternoons. Fire heat will only be necessary to maintain the night temperature at 40°, a couple of degrees less being better than over that temperature at night; 50° in the daytime is suitable, from

above which ventilate, allowing a free circulation when the temperature is above 55°. Employ no fire heat unless it is absolutely necessary, and even then be sparing, as too much in the early stages is fatal to the prospect of a crop of fruit.

FORCING HOUSE.

The demand for flowers for indoor decoration has greatly increased of late years, the gardener often experiencing much difficulty in keeping pace with the demand; and though many plants can be brought into bloom in the stove and are attractive, yet some are totally unsuited for cutting and decorative purposes, as they cannot be removed to the colder and drier atmosphere of rooms. Hence the necessity of selecting such as naturally flower early, and can be forwarded with little fire heat in a light airy house and a temperature of 55° to 65° artificially. If there is a pit that can be filled with fermenting leaves it will be an advantage, lessening the necessity for fire heat, and affording mild bottom heat to such plants as Lily of the Valley and Tuberoses. In order to supplement the regular supply of flowers afforded by the winter and spring-flowering occupants of the stove and greenhouse, a forcing house for such as the following is essential to meet the demand. For the conservatory Rhododendrons are unrivalled, selecting those that flower early, as *Nobleanum*, *caucasicum album*, *limbatum*, *coriaceum*, *Purity*, *altaclerense*, *cardinale*, Mrs. John Clutton, Michael Waterer, Lady Armstrong, Cynthia, Everestianum, Seipio, Mrs. Fitzgerald, Glenneanum, Broughtonianum, Sir Robert Peel, Mars, &c., not omitting Early Gem and fragrans. For association with Rhododendrons Azaleas are indispensable, producing bright sweet flowers for cutting, especially *A. pontica*. *A. mollis* and its varieties are superb, and should be grown by everyone, but for durability the double *narcissiflora*, yellow; Graf van Moran, pink; and Van Houtte, yellow and red, are matchless, and hold a high position for forcing. *Kalmia latifolia* and *K. myrtiflora* afford elegant delicate waxy flowers, and are usually much appreciated. *Laurustinus*, with its natural disposition to bloom during the winter, is easily induced to open its flowers in a little heat; much may be written in its favour, indeed plants are beautiful in the conservatory. Lilacs are, of course, very useful; Charles X. has large flowers, but to be white requires to be grown in the dark, the common white and Persian Lilac not needing such treatment. The Guelder Rose is valuable for forcing, but finer still is the Japanese *Viburnum plicatum*, having globular heads of white flowers. The double Plum (*Prunus sinensis alba flore-pleno*), is useful, but not equal to the indispensable *Deutzia gracilis*, which is likely to find a rival in *Staphylea colchica*, its terminal panicles of white flowers being extremely ornamental. *Spiræa Thunbergi* flowers very profusely, but is not of great endurance. Sweet Briar is usually in request for its scent and sprays for cutting. *Daphne Cneorum major* is also valued for its rosy pink deliciously scented flowers, but it must not be brought on too quickly. *Dielytra spectabilis* is fine for any purpose. Pinks are always acceptable, and should be assigned positions near the glass. Blue is a colour by no means common in forced plants, but it is readily afforded by *Myosotis dissitiflora*, which blooms for a long time in a light airy position in a temperature of 50°. *Hoteia* (*Spiræa*) *japonica* cannot be too highly extolled; no other plant is more elegant and graceful, nor endures more cutting. A first batch of the above-named plants should be introduced, damping them occasionally overhead on bright afternoons, and available surfaces two or three times a day, commencing with a temperature of 50° artificially, increased in a fortnight to 55°, allowing an advance from sun heat of 10°. Plants of every description, even if hardy, intended to be forced should at once be protected from frost, as there is no advantage in allowing them to become frozen.

Where Hyacinths and Narcissuses are required early a few of the earliest potted may be placed in heat. They should be assigned positions near the glass; but if they have only recently been removed from the usual plunging bed of ashes they must not be at once submitted to the full influence of light, or the growth will be crippled; small flower pots inverted over them will at first admit enough light through the hole in the bottom, tilting the pots after a few days, and when the advancing growths have gradually become green remove the pots altogether. Crocuses must be allowed to come on

gradually, being kept near the glass in a temperature of about 50°. Scillas should be treated similarly. Lily of the Valley must be introduced at intervals to maintain the supply. At this early season bottom heat (80°) is essential to certain growths, especially for imported crowns or clumps, covering them about 2 inches deep in the plunging material, and when the flower spikes appear invert flower pots over them until the spikes are 5 or 6 inches high, when the pots can be removed, and exposure to light will soon give the flowers substance.

NOTES ON VILLA AND SUBURBAN GARDENING.

PLANT HOUSES AND FRAMES.

Hints upon Watering.—One of the greatest difficulties with inexperienced plant-growers is not being able to determine when a plant should or should not be watered. No matter how well the plants may be potted, if they be either neglected or supplied too freely they will not thrive, and in many instances will be completely ruined; hence the necessity of the grower studying their habits and attending closely to their respective requirements. Very frequently the owners of plants supply them with water regularly, and seem surprised when told that this is the real cause of failure. Among the working classes window plants are much prized, and are often well grown when once the art of watering is understood. Regular watering sometimes means giving daily dribbles; this is a very faulty practice, and equally so is that of filling the pots too full of soil, instead of allowing the depth of the rim of the pot. In this case the surface of the soil is soaked regularly while that part of the soil where the roots are gradually becomes dust dry, which nothing but an immersion in a tub of water will moisten. Although many plants can be restored to healthy vigour after being injured by drought at the roots—more so, in fact, than is the case with the opposite extreme—it is still a common cause of failure with *Cinerarias*, *Cyclamens*, *Calceolarias*, *Fuchsias*, *Salvias*, *Solanums*, *Balsams*, *Chrysanthemums*, *Callas*, *Camellias*, *Azaleas*, *Ericas*, *Bouvardias*, *Libonias*, and many more. None of these should ever be allowed to flag, as they will be considerably checked if not fatally injured thereby.

It is difficult to lay down any rules as to the proper time for watering, as so much depends upon circumstances. Hardwooded plants, which usually have very fine roots and are potted very firmly, require the greatest amount of judgment, as they are the most easily injured by either extreme. With the coarser-rooted plants the test of sharply rapping the pots with the knuckles is generally a safe one (the soil being dry the pot gives a somewhat empty sound); but if watering is delayed till the pots containing Heaths and Azaleas sound at all empty the chances are that many of the roots will be killed. To test these the small plants may be lifted to try the weight, and the larger judged either by the dry appearance of the soil or by feeling, and even by loosening the surface slightly. Sufficient water should always be given to thoroughly moisten the soil, so that at least a small quantity shall pass through the drainage. Owing to small shifts being given to this class of plants they are frequently potted rather high, so that but little water can be given at a time, and therefore a second supply is often needed to ensure complete moistening. If by chance any of these be found excessively dry, at once immerse them for at least thirty minutes in a pail of tepid water.

Never use water quite cold, nor, on the other hand, very warm water, as this may give a check to the roots should the temperature be low where the plant is growing. The safest rule would be to always use water raised slightly above the temperature of the house, room, or frames, and the softer the water is the better for the well-being of the plants. Much caution is required at this time of year when watering plants in unheated structures, as they lose but little moisture by evaporation; neither do the pots absorb moisture from the soil. In this case it is best to keep them a little drier than usual, watering only when necessary to prevent the foliage drooping. Bedding Pelargoniums at the present time do not require water if in a cool house or frame, as they should not be induced to grow for at least two months to come. The less fire heat they have beyond that employed to keep out frost or prevent damping the better; the same remarks apply with equal force to *Cinerarias* and herbaceous

Calceolarias, which under these circumstances will not require water very frequently—certainly not daily. Where fire heat is used to maintain a suitable temperature, Solanums, Callas, Salvias, Eupatoriums, Browallias, Abutilons, and others will require liberal waterings almost daily, especially if they are near the hot-water pipes or flues; but if the temperature during the night falls much below 50° delicate plants, such as Coleuses, Iresines, Alternantheras, and Mesembryanthemums, must be very sparingly watered or they will succumb.

In the case of Fuchsias, and indeed all deciduous plants in a resting state, give water often enough to prevent the wood from shrivelling. The wood must be plump as well as ripened. The Maidenhair Fern (*Adiantum cuneatum*) should now be resting—that is to say, should be in a somewhat cool house, and receive only sufficient water to keep the plants alive, as this will insure a strong even start in the spring. *Adiantum formosum* must also be watered sparingly if in a cool house, but in a stove may be kept steadily growing. *Adiantum farleyense* should be in a light but cool part of the stove, and be also watered carefully, or premature growth will ensue. *Caladiums* may be placed as near the hot-water pipes as possible and kept perfectly dry, the *Gloxinias* also to be kept dry and in a cold house, the same remarks applying to tuberous-rooted *Begonias*. *Begonia Weltoniensis* may be kept in a moderately heated greenhouse, or even in a window, provided only sufficient water is given to prevent the stems shrivelling. The winter-flowering *Begonias* require a stove temperature, and should not be allowed to become very dry at the roots. *Stephanotis* and *Allamandas* must now be resting or ripening, but the latter particularly ought not to be dried too much at the roots. *Plumbago capensis* may be rested in a cool house—where, indeed, it is usually grown. *Crotons* and *Dracenas* may be kept somewhat dry at the roots, though not to such an extent as to cause the leaves to fall. Young plants of these may be kept steadily growing. *Eranthemums*, *Poinsettias*, *Plumbagos*, *Begonias*, *Euphorbias*, and other plants that may be taken from a stove and placed in a cooler structure or room, should be watered with the greatest caution; in fact, they may be kept comparatively dry.

TRADE CATALOGUES RECEIVED.

William Fell & Co., Hexham, Northumberland.—*Catalogue of Trees and Shrubs*.

Putz & Roes, Erfurt, Prussia, and 50, Great Russell Street, London, W.C.—*List of Seeds*.

L. Späth, Berlin.—*General Catalogue*.

Corry, Soper, Fowler, & Co. (Limited), Finsbury Street and Shad Thames, London.—*Trade Price List of Nurserymen's Sundries*.

* * All correspondence should be directed either to "The Editors" or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Address (Subscriber).—If you write to Messrs. Ransomes, Sims, and Head, Ipswich, you will obtain the information you require.

Books (Inquirer and Field).—The work you have is a good one. You would find the "Cottage Gardeners' Dictionary" very useful. The names of the plants are accentuated as an aid to their correct pronunciation. A revised edition with a supplement of this work is in course of preparation, and the publishers inform us that it will be ready in the course of a few months.

Potting Hyacinths (J. B.).—The bulbs ought to have been potted a month ago. You must not lose a day in potting them, or they will not flower soon enough for your purpose. We cannot name plants from crushed and imperfect portions of the leaves alone.

Myatt's Ashleaf Potato (H. M.).—It was raised by Jas. Ashwin, Esq., Bretforton Hall, Evesham, by whom it was given to Mr. Myatt, an extensive

market gardener in the neighbourhood. Mr. Ashwin also gave it to Mr. Rivers of Sawbridgeworth, and he named it, for the reason stated in page 439, the Royal Ashleaf. Eventually it was placed in commerce by Messrs. Wrench under the name of Rivers' Royal Ashleaf, as they had the stock from Sawbridgeworth; but Mr. Rivers always disclaimed the right of his name being attached to this Potato.

Tydaas (J. P.).—You may gradually reduce the water after the plants have flowered, but withholding it suddenly and entirely is not sound practice. We shall publish notes on the culture of Tydaas in an early issue.

Cypripedium insigne (B. T. J.).—It is not common for two flowers to be produced on one stem, yet we have seen several examples on plants that, like your own, have been unusually well grown. We never saw a finer example of good culture than the flowers you have sent. We should hesitate to cut up the plant, as the check that would necessarily be given would prevent similar flowers being produced for some time; still, if you can separate the portion to which you refer without greatly disturbing the roots, you might succeed in your object.

Otterspool Brussels Sprouts (Inquirer).—In the trial of Brussels Sprouts at Chiswick this year the Fruit and Vegetable Committee of the Royal Horticultural Society decided that the "Aigburth" from Messrs. Ker & Co., of Aigburth near Liverpool, and the variety above named are identical.

Heating a Tank (W. M. L.).—Your sketch is unintelligible, but if you raise the tank above the pipes, and take a branch from the flow pipe through the tank, and connect it with the same pipe at a higher point or beyond the tank, the water in the pipe will circulate freely and heat the water in the tank. If the tank is small a 2-inch pipe will probably be sufficient, but if large a 3-inch pipe will be preferable; the size of pipe, however, must be determined by the extent to which the water in the apparatus is usually heated.

Vine Roots (C. B. M.).—The Vines have been carefully examined. There were no Phylloxera on them, and no signs of any having been there; indeed there were no insects at all on the portions we examined. Your representative has, however, informed us that insects have been seen on the roots, and if you will send us some of these insects they shall be carefully examined. The roots appear as if they had been in contact with some corrosive substance, still by your description the border appears to have been made correctly. Is there iron in the loam? Gas ammoniacal liquor is a powerful stimulant, and mixed in proportion of one pint to two gallons of water is safe for many crops. We do not know whether it will kill the Phylloxera, not having tried it with that object.

Wire for Vineries (T. W.).—Galvanised wire may be safely employed provided it is well painted, three coats being given in the first instance, and a fresh coat annually. Unpainted it is very injurious in some places, but not in all. Something will be published shortly on the injury resulting from this wire in some cases and not in others. Copper wire is quite safe, but much more costly than galvanised wire. We should not hesitate to use the last-named wire, keeping it well painted.

Chrysanthemum Culture (Old Subscriber).—As you are an "old subscriber" and yet "do not recollect having seen any information on the above subject," we fear you are not an attentive reader. Many articles on the subject have appeared; and if you send stamps to the publisher and ask him to send you Nos. 819, 820, and 977, you will find details for growing specimen large-flowered varieties, specimen Pompons (both illustrated), and blooms for exhibition. The price of the three numbers is 10½d. The articles referred to are written by excellent cultivators and successful exhibitors. The subject will be further alluded to in due time.

Propagating Chrysanthemums (L. H. S., Clapham Park).—If you place the plants in a light position in a warm greenhouse they will afford cuttings that will strike readily in January in a moderately heated propagating house. When rooted the tops of the plants can be taken off, and in the meantime the stock plants will afford successional batches of cuttings to be inserted as soon as large enough. By continuing this practice until May a great number of plants can be raised from a few old stools. Cuttings, or rather offsets, will strike if inserted now and the pots plunged in ashes in a frost-proof frame, but as your object is to raise as many plants as possible the plan above indicated will be preferable.

Cornflowers (Idem).—There are several pretty varieties, but the one most suitable for your purpose is, we think, *Centaurea Cyanus major*. Seed sown in good soil and a favourable position in the open ground during fine weather in February or March will produce early-flowering plants; or if a little seed is sown in pots in a greenhouse, the seedlings being thinned out and grown on a shelf close to the glass for a time, then prepared in a frame for planting out about the end of March or early in April, the plants if well managed would flower still earlier than those from seed sown in the open air. You may sow in pots now or in January. The earliest and best plants are produced by sowing in September and affording the plants the protection of a cold frame if needed during the winter.

Roses (A Subscriber).—We will readily comply with your request and name "some good Roses," but as we do not know whether you require a dozen or a hundred we are unable to submit a list that will be serviceable to you. Correspondents when requesting selections of varieties of flowers or fruit should in their own interests state the number they need. It is of no use our publishing fifty names when twelve would suffice, and to publish the smaller number when the larger is required would cause disappointment.

Fruits for a Cold District (W. W. A.).—We think you would derive advantage by noting those varieties that usually succeed well in your district and plant them. Local nurserymen are usually acquainted with the sorts that give the greatest satisfaction in the locality in which they are interested. Judging from your letter we conclude that no very late varieties of Apples and Pears could be depended on, and those that are moderately early in favourable localities would prove late with you. Dessert Apples that we think would be likely to succeed are Devonshire Quarrenden and Cox's Orange Pippin; kitchen Apple, Tower of Glamis. Pears—Jargonelle, Marie Louise d'Uccle, and for stewing Catillac. Cherries—Early Rivers and Kentish. Plums—Oullins Golden and Victoria. The Pear you sent shrivelled instead of ripening, and we are unable to identify it; it resembles a stunted specimen of *Beurré Diel*. Thanks for your letter.

Wintering Echeverias and Kleinias (M. M.).—Let the Echeverias remain where they are, giving them but little water. The offsets may be removed in the spring soon after the vinery is started, and be planted in boxes of gritty soil, which should be kept moist to promote their growth. They should be sorted into sizes, so that the large and small are not mixed together in the boxes. It is important, too, that this principle be adopted when planting them in the flower

garden. The *Kleinias* should be placed on a shelf in a warmer house, and watered to prevent their shrivelling. A warm greenhouse is suitable, and they may be afforded more heat as the spring approaches to encourage the growth of the plants and to afford cuttings. The leaves will also emit roots and form plants if very slightly inserted in sandy soil in August, or as soon as the leaves have attained their full size. This mode of increase is only necessary when a large number of plants are required, as in the London parks, where the system is adopted.

Pruning Vines (X. F.).—If the young canes to which you refer are strong, well ripened, and have prominent buds they will no doubt fruit freely, but whether they will afford better results than the old rods would depend entirely on the condition of the Vines and laterals. If the old rods do not produce satisfactory crops by all means retain a portion at least of the young canes. If you leave these canes their entire length they may probably not produce strong laterals towards the base; and the result would be, that although you obtained a good crop of fruit this year, the Vines would not be satisfactory next year, as the lower portion of the roof would not be well covered, except—and this is a very important exception—you train up other young canes from the base for fruiting next year, removing those that have borne fruit entirely, or divesting the lower portion of the weak buds, the young canes being relied on for producing fruit along the bottom of the house. The upper portion of the roof would then be furnished with two-year-old rods, and the lower portion with one-year-old canes. Another plan is to shorten the young canes, leaving them about 4 feet long, and remove the spurs from the old rods to that height, and continue the practice until the roof is covered with young canes, the old rods being removed entirely in two or three years. You will thus renew the Vines without losing a crop. If the old rods bear fairly well this would be a good practice to adopt.

The Mango and Custard Apple (C. B. A.).—The seeds might be sown now, but the young plants produced would be more likely to succeed if the sowing be deferred until early in spring. The soil should consist of finely sifted light loam and silver sand, which may be placed either in pots or shallow pans, the latter being preferable. The drainage should occupy two-thirds of the pans, and these must be plunged in a hotbed under a propagating frame or bellglass, the seeds being slightly covered with the compost and gently watered with tepid water through a fine rose. If the seeds are good they will soon germinate, and when the young plants have attained a suitable size they must be carefully removed and potted singly in small pots, employing a richer soil, and placing them in the warmest portion of the stove, where they can be shaded until growing freely. The plants can afterwards be shifted as they increase in size.

Various (Paddle).—The *Aloes* you mention are quite distinct and very easily recognised, and to enable you to determine whether those in your possession are really *Aloe distans* or not we subjoin the following brief descriptions of the two species:—*A. distans* has thick fleshy leaves 2 inches broad at their base and 3 inches long, tapering to an acute point. They are rather distantly placed on the stem, as the name implies, are of a dark green colour, and have marginal rows of white spines about one-eighth of an inch long. *A. mitriformis* is much more compact in habit, the leaves being more closely set and less fleshy than those of *A. distans*. The leaves are 3 or 4 inches broad at the base, 4 to 5 inches long, tapering, and slightly hollowed on the upper surface. On the margin there are a few spines generally, but little more than one-sixteenth of an inch in length. *Mesemhryanthemum tigrinum* is one of the most distinct and attractive in the genus as regards the foliage, and could not possibly be confounded with such forms as *M. deltoideum* or any other species. It is most nearly allied to *M. lupinum* and *M. felinum*, but is very easily distinguished even from them. We are unable to recommend nurserymen who make a speciality of succulent plants; those who have plants for sale should advertise them. The glands of Peach leaves are found near the base of the blade or on the petiole, being either slightly stalked or sunk in the substance of the leaf. The characters derived from the forms of these glands are employed in the classification of the Peaches.

Chrysanthemum Sport (Chrysanthemum).—The sport is a remarkable one, as having been produced by Dr. Sharpe. The flower is creamy with a suspicion of pink on the reverse of the florets, which are broad and incurved at the tips like those of Mrs. George Rundle. In character the flower, however, resembles White Globe. The example before us is thin and flat, and if larger and fuller blooms cannot be obtained the variety will have little commercial value; but we think with high culture much finer flowers may be produced. Grow some plants well next year, disbudbing them early, and retaining about three flowers on each plant, and exhibit the blooms at some of the Chrysanthemum shows, and before the Floral Committee of the Royal Horticultural Society.

Pruning Vines (B. E. W.).—We think the plan you suggest is the best under the circumstances. Train up a young cane from the base of each Vine, and allow it to have all the light possible next summer. As the spurs on the old rods are so far apart we should secure the laterals to the main rods, and shorten them to bold buds that will grow outwards from the rod, not inwards. The wood that is left must be ripe and firm. In the spring rub off the superfluous growths when they are an inch long, or as soon as the bunches are perceived, leaving the more promising, which should be quite 15 inches apart. You will obtain more fruit by this mode than by close pruning, and in two years the old rods may be removed. If your Vines are free from insects do not peel the rods; but you cannot err by washing them with a solution of soft soap or Gishurst compound at the strength of 5 or 6 ozs. to the gallon of water, applying it as hot as can be borne by the hand with an old spoke brush. Any loose bark that is displaced by the scrubbing may be removed, that is all. Your other question shall be answered next week, which will be in ample time for your purpose.

Roman Hyacinths (W. R.).—They are of little value for forcing during a second season; they scarcely pay for the trouble. When carefully managed they only yield a small per-centage of flowers useful for cutting. To be of any use after flowering liberal applications of liquid manure must be given, and the foliage kept fresh as long as possible, and the pots then placed outside. When the foliage has died down all that is needed is to keep the bulbs moderately dry until the end of August or beginning of September. They can then be repotted and treated as new bulbs, or, better still, placed thickly together in pans purposely for affording small spikes for cutting. They can also be planted out of doors, but care is required in preparing the plants, which must not be planted before the end of March at the earliest.

Market Prices (S. C.).—The extract you have sent and marked No. 1 is a copy of what appeared in the *Times* of the previous week; the other is from a penny daily paper. Both are glaringly inaccurate in several particulars, that must be obvious to any intelligent gardener. Cabbages are quoted from 2s. to 4s. per dozen, which is 150 per cent. above their selling value, as hundreds of growers know to their cost. Asparagus at the time the reports appeared was

not in the market at all. But we cannot afford space to dwell on all the inaccuracies in the extracts you have sent to us. The reports may have been correct at the time they were written, but they do not appear to have been altered with the change of seasons and of prices. You mention fruit, and especially Grapes. The prices quoted for several kinds of fruit are incorrect; for instance, Apples, Oranges, and Pine Apples—that is, accepting them without qualification. Grapes, which you specially mention, are 100 per cent. above the average prices that are given for the fruit, and it is the selling price in which you and our readers generally are interested. For extraordinary fine samples and for special purposes 10s. or more per pound are very occasionally obtained for Grapes, just as some remarkable Apples have been sold this year for 5s. each; but these prices do not represent the actual state of the markets. The prices of "large bunches" on which you ask for information probably represent some sensational exhibits which some tradesman has placed in his window, and to which he has attached a sensational price. You have good reason to be satisfied with the prices you have obtained, for they are 1s. a pound more than one of the most celebrated of British Grape-growers has realised for his produce. Grapes are really selling from 6d. to 10s. per pound in Covent Garden, but the latter price is only obtained for special samples required for special purposes, the bulk of the produce being sold at from 2s. 6d. to 7s. per pound, and of course purchased for less sums. Such lists as you have sent to us have evidently not been corrected for some time, and cannot fail to cause disappointment to those who have produce to sell.

Names of Fruits (John Shepherd).—1, Warner's King; 2, Winter Colman; 3, Red Ingestrie; 4, Northern Greening; 5, Cox's Pomona. (*T. S.*)—1, Thompson's; 2, Duchesse d'Angoulême; 3, General Todtleben; 4, Beurré Diel; 5 was quite rotten. The Apple is Golden Winter Pearmain. (*H. P.*)—Beurré Diel, in excellent condition.

Names of Plants (Tonbridge).—1, *Platyloma rotundifolia*; 2, *Blechnum spicant*; 3, specimen insufficient for identification, but it resembles *Blechnum longifolium*; 4, *Pteris umbrosa*. (*No Name*).—1, *Cyrtomium falcatum*; 2, *Phlebodium sporodocarpum*; 3, *Adiantum hispidulum*; 4, *Blechnum brasiliense*; 5, *Scolopendrium vulgare cristatum*.

POULTRY, PIGEON, AND BEE CHRONICLE.

CLOVER AS A PREPARATORY CROP FOR WHEAT.

THE causes of the benefits to be derived from Clover as a preparatory crop for Wheat were formerly hidden in much obscurity, for although some of the best practical farmers found from experience much advantage in growing Clover previous to the Wheat crop, they were totally at a loss to account for it chemically. In the year 1868 Dr. Voelcker related his researches and experiments in a long and interesting essay upon the subject in the "Journal of the Royal Agricultural Society of England," and for the benefit of the home farmer we shall endeavour to lay before him not only quotations from Dr. Voelcker, but also our opinions and experience.

To have the full advantage of a Clover crop it should be grown alone. We refer particularly to the red-blossomed Broad Clover, because if grown with common Rye Grass or other Grasses we neutralise to a certain extent the benefits which would otherwise be obtained. It is also of so much importance to secure a regular plant of Clover that it is necessary to prepare the land and arrange the rotations of cropping for the purpose. It is well known that with few exceptions a full plant of Clover cannot be obtained by sowing it every four, five, or even six years—that is to say, once in every rotation; but it is usual and advisable to alternate this crop with Beans, Peas, or other leguminous crops, it being a well-ascertained fact that these are a better preparation for the cereals than the ordinary lea ground after a hay crop composed of mixed Grasses, as nearly all of these extract from the land the important elements and manures required by the cereals. After we have obtained a regular plant of Broad Clover it is of great importance that the crop should be encouraged in growth as much as possible by manures, and also protected from unfair and injurious feeding by sheep. It is of consequence, too, that the autumn growth in the first year should be promoted as much as possible. This is not customary, for the Clover is generally sown in Lent corn; but we prefer to have it in the Wheat, in order that it may grow more vigorously whilst the corn is maturing, and

also that it may not be cut so closely when the corn is reaped. We have found it profitable to cut the Wheat higher up the straw, in order that the Clover may make an after growth fit for mowing in the autumn, and we have obtained excellent Clover fodder to cut up for horses and other animals during September and October, and until the first severe frost occurs. Again, this is not only a profitable plan—available when Wheat follows a Potato, Mangold, or other root crop—in four years out of six in the southern or south-eastern counties; but it encourages the growth and strength of the Clover roots, and enables them to yield a larger increase of hay in the succeeding year, whereas if the young seeds had been treated in the ordinary way by close feeding with sheep the crowns of the plants and future buds would have been destroyed or seriously injured, and the Clover plants so much damaged that many of them would die. This leads us to a point which we shall be prepared to prove of the highest importance—namely, the growth and greatest increased weight of the roots of the Clover plants.

We must at the same time look to the management of the Clover lea after the hay crops, or even crops of seed, have been removed. On certain mixed soils it is very difficult to insure a Clover lea free from Couch Grass; it is therefore necessary that every opportunity should be taken to fork-out single bunches of Grass. This must be done not only in the root crops before the corn, but also in the young Clover seeds, in order that the land may not require cleaning as a Clover lea. There are various modes of doing this. A backward fallow, for instance, after the first hay crop, is often resorted to, or the land sometimes scarified and tilled just before the final ploughing of the lea. The point we wish to enforce is that the tillage of a Clover lea cannot be done without destroying the Clover roots to some extent. The roots of Couch may be forked-out by hand labour, as we have often done. If any horse labour is used to root out Couch it should be done by the scarifier, but only with the points on, so that the Clover roots may be left, if not wholly, yet the greater portion of them. Couch Grass is our greatest enemy in all agricultural operations; and if we allow it to remain in the Clover lea and plough it in, it so competes with the Wheat crop that a full crop is out of the question. Dr. Voelcker shows us that the food which the Clover root furnishes for the Wheat plant is also available for its enemy.

We will commence our quotations from Dr. Voelcker's essay where he says, "The fact is well known that many farmers justly regard the growth of Clover as one of the best preparatory operations which the land can undergo, in order to its producing an abundant crop of Wheat in the following year. It has further been noticed that Clover mown twice leaves the land in better condition as regards its Wheat-producing capabilities than when mown once only for hay and the second crop fed off on the land by sheep; for notwithstanding that in the latter instance the fertilising elements in the Clover crop are in part restored in the sheep excrements, yet, contrary to expectation, this partial restoration of the elements of fertility to the land has not the effect of producing more or better Wheat in the following year than is reaped on the land from off which the whole Clover crop has been carried, and to which no manure whatever has been applied. Again, in the opinion of several good practical agriculturists with whom I have conversed on the subject, land whereon Clover has been grown for seed in the preceding year yields a better crop of Wheat than it does when the Clover is mown twice for hay, or even only once, and afterwards fed off by sheep. Most crops, I need hardly observe, when left for seed exhaust the land far more than they do when they are cut down at an earlier stage of their growth, hence the binding clauses in most farm leases which compel the tenant not to grow corn crops more frequently nor to a greater extent than stipulated. However, in the case of Clover grown for seed we have, according to the testimony of trustworthy witnesses, an exception to a law generally applicable to most other crops. Agricultural experiences contradicting prevailing, and, it may be, generally current theories, are, unless I am much mistaken, of far more common occurrence than may be known to those who are either naturally unobservant or unacquainted with many of the details of farming operations; indeed, an interesting and instructive treatise might be written on the apparent anomalies in agriculture.

"Observations extending over a number of years led me to inquire into the reasons why Clover is specially well fitted to prepare land for Wheat, and in the notes which I have now the pleasure of laying before the readers of the Journal I shall endeavour, as the result of my experiments on the subject, to give an intelligible explanation of the fact that Clover is so excellent a preparatory crop for Wheat as it is practically known to be. By those taking a superficial view of the subject it may be suggested that any injury likely to be caused by the removal of a

certain amount of fertilising matter is altogether insignificant, and more than compensated for by the benefit which results from the abundant growth of Clover roots and the physical improvements in the soil which take place in their decomposition. Looking, however, more closely into the matter, it will be found that in a good crop of Clover hay a very considerable amount of both mineral and organic substances is carried off the land, and that if the total amount of such constituents in a crop had to be regarded exclusively as the measure for determining the relative degrees in which different farm crops exhaust the land, Clover would have to be described as about the most exhausting crop in the entire rotation. Clover hay on an average and in round numbers contains in 100 parts:—

Water	17.0
*Nitrogenous substances (flesh-forming matters)	15.6
Non-nitrogenous compounds	59.9
Mineral matter (ash).....	7.5
	100.0
*Containing nitrogen	2.5

The mineral portion or ash constituents in 100 parts of Clover hay consist of phosphoric acid, 75; sulphuric acid, 4.3; carbonic acid, 18.0; silica, 3.0; lime, 30.0; magnesia, 8.5; potash, 20.0; soda, chloride of sodium, oxide of iron, sand, loss, &c., 8.7; total, 100.0.

"Now let us suppose the land to have yielded 4 tons of Clover hay per acre. According to the preceding data we find that such a crop included 224 lbs. of nitrogen, equal to 272 lbs. of ammonia, and 672 lbs. of mineral matter or ash constituents; 4 tons of Clover hay, the produce of 1 acre, thus contain a large amount of nitrogen, and remove from the soil an enormous quantity of mineral matters, abounding in lime and potash, and containing also a good deal of phosphoric acid."

(To be continued.)

WORK ON THE HOME FARM.

Horse Labour.—Horses have lately been employed in ploughing and sowing Wheat every day since the 28th ult., there only now remains the light land to be ploughed and sown with Wheat. Apportion the horse power of the farm so that no ploughed land shall be left unsown in the evening in consequence of the night frosts which are sure to prevail at this time of year. We notice much land which has been under autumn tillage lying in a very foul state with abundance of couch grass on the surface. It is not good practical farming to plough this grass under with a deep furrow; the only plan to adopt is to rafter-plough and leave it until the spring, for at this date there is no hope of dry weather to enable the grass to be cleared off the surface by tillage. Where the land is clean, deep fallow-ploughing of all the land intended for Barley after Wheat will be going on daily whilst the weather continues open. The same plan will be pursued with land intended for the next year's Mangolds, Carrots, Potatoes, and Swedes. Long fresh dung may be laid out before the ploughing on good dry land for the Mangolds, Carrots, and Potatoes, especially as this will save labour of the horses in the busy period of spring and seed time. In many instances, the slugs having destroyed the Trifolium, the land may be ploughed and lay during winter to be worked fine the first dry weather in the spring, and again sown with the Early Crimson Trifolium or with summer Vetches. The land which has been dunged and ploughed if clean will require no more ploughing in the spring, but merely scarifying and sowing with Mangolds and Carrots at the earliest date.

Hand Labour.—The land occupied with Cabbages that has been autumn-planted should now be locked over whilst the weather is mild, and vacancies filled with fresh plants, as the crop will come better together than when fresh plants are set out in the spring. The water meadows must still be attended to, and the course of the water changed every four or five days, especially on those meadows where the supply of water is short. The land, if strong and flat, where the Wheat has been sown should be looked over by men with spade in hand after heavy rains to let off any accumulations before it injures the Wheat. Hedging, ditching, and banking will now be necessary in the enclosed districts of small fields. In those cases where fences are required to be newly planted with Whitethorn, this is a good time to do the work. Any hedges, too, intended for close trimming, where they have been neglected may be cut down and trimmed. The outlets of all underground draining should be carefully attended to, and they will easily be found by the men whilst scouring the open dykes, which ought to be well opened and cleansed at this time, so as to give free exit to flood water. All the young cattle intended for dairy stock should now be placed in sheltered yards and sheds at night; and although they may run out in the pasture at daytime, they should receive roots of some kind with sweet fresh Oat or Barley straw in the sheds. This feeding will keep them in moderate condition, and by lying in well-littered sheds it will prevent attacks of the quarter-ill, which in some seasons is very fatal amongst young heifers reared for the dairy. If any cake is given it should only be decorticated cotton cake in meal and mixed with cut roots, or with inferior hay cut into chaff. It is, however,

just a question of price whether inferior Barley in meal may be substituted for cake. All the yearling steers intended to be fattened on the system of early maturity should now be fed in the same boxes as they have been kept in during the past summer, for although they have had full allowance of green fodder as long as it lasted, they will now receive roots with cake and beanmeal mixed, from 40 to 50 lbs. of roots being sufficient for the day's allowance, with plenty of sweet Oat straw in the racks, the refuse to be used for littering the boxes. The manure removed from the cart-horse stables is too often allowed to remain in large heaps in the open, exposed to all weathers. Sometimes it is too dry, at other times too wet. Our plan of using the partially stained straw from the stables as litter for the pig pens answers a good purpose, for it not only saves straw, but it makes the manure more valuable after being trodden down and concentrated in the pig pens for a while. Where there is no covered dung pit it is well to have the manure as it comes from the stables cast into a yard where breeding sows may be kept, and thus the manure is trodden down, and the sows kept in a healthy breeding condition, with a hovel to lie in attached to the yard.

THE SMITHFIELD CLUB CATTLE SHOW.

THE Show that opened in the Agricultural Hall, Islington, on Monday last was, if not the largest, certainly the best that has been held there, judged by the average high quality of the animals exhibited. The very slight decline in the number of animals is due to a new and very commendable regulation that no animal over four years of age have admittance. Early maturity, not old stock however famous, is obviously what is required at exhibitions of this nature. The Show will be remembered not more for its general excellence than as having afforded the public an opportunity of inspecting one of the most magnificent animals that has ever been exhibited—the three-and-a-half-year-old steer with which Mr. Colman, M.P., won the champion plate of 100 guineas. It is a light roan, and was bred by Mr. James Durne of Old Meldrum, and is the result of a cross between a Shorthorn bull and an Aberdeen cow; it weighs a little over a ton, is almost faultless in form, and in prime condition. The same animal also won £25 as the best of his class, £40 in the best of his breed, £50 as the best of his sex, which, with £105 as the champion prize, makes a total of £220. Mr. Colman also won several other valuable prizes. The silver cups, value £40, were awarded as follows:—For Devons, to Mr. John Walter, M.P.; for Herefords, to Mr. F. Platt; for Shorthorns, to Mr. C. T. Lucas; for Sussex, to Mr. J. S. Oxley; for Scotch, Mr. Colman, who had similar awards in two other classes. All the cup animals were splendid, and many others were of nearly equal merit.

The sheep as a whole are a grand lot of animals, not so bulky and unwieldy as we have seen, but smart, fresh, and of undeniable quality. The cups were awarded to the executors of the late Mr. Painter for Leicesters, to Mr. J. Craddock for Cotswolds, to Mr. Pears for Lincoln, to Mr. Page for Kentish, to Lord Walsingham for South-downs, to Mr. Morrison for Wiltshire or Hampshire Downs, to Mr. Nock for Shropshires, to Mr. Cooper for Oxfordshire Downs, to Mr. Stranger for Cheviots, and to Mr. Farthing for Dorsets.

Pigs are numerous and admirably represented, attracting crowds of visitors. The cup for the best pen of any small white breed was won by the Earl of Radnor; for any large white breed by Messrs. J. & F. Howard; for black pigs by Mr. J. A. Smith; and for Berkshires by Mr. Fowler. The Queen is a prizewinner in this section of the Show.

Collections of roots are an important feature of the Show, all the leading agricultural seedsmen being represented. Messrs. Sutton and Sons have a large and imposing stand artistically furnished with splendid produce; Messrs. Carter & Co. have superior sample roots on view, and a refreshing verge of Grass growing from recently-sown lawn seed; Messrs. T. Gibbs & Co., Messrs. Webb & Sons, Messrs. Harrison & Sons, Mr. King, and others have large and excellent displays, and Messrs. Hooper & Co. a fine collection of Potatoes.

Machinery, implements, farming appliances, and household requisites of all kinds, with manures, are represented by nearly all the leading manufacturers in the country. The Exhibition, which is well managed throughout, closes to-morrow (Friday) night.

THE POULTRY CLUB.

We published a few weeks ago some important resolutions to be submitted to the general meeting of the Poultry Club, which were in the main carried. To some extent this marks a new departure in the history of the Club, and is therefore worthy of consideration. We will not now go into all the proposed methods of extending the Club's influence; that which at present claims our attention is the passing of a resolution to the effect that a circular relating to the objects of the Club is to be sent round to some seven thousand fanciers! The fact cannot fail to strike us, that the Club has survived to enter upon a new phase of its existence; no other similar poultry club has, to the best of our knowledge, ever reached this stage. Those we can recall to mind have had a year of organisation and popularity, and then a year of dissolution and decay. The present Club has lasted

three years, and is so far from extinction that it is about thus to invite public attention to its existence. Hitherto it has been extremely quiet. The now defunct Club occupied itself much with formalities; but red-tapeism has not been the error of this Club, and probably this is one of the reasons of its survival. Its numbers continue about the same as a year ago, but they do not increase. This is perhaps to be regretted, and is probably the reason why the said circular is to be issued. There are, we are sure, a large number of honourable fanciers without the Club who wish all success to its objects, and whose names would add influence to its list. Why they should hold aloof from it is a subject well worthy of consideration. Of course there are others who have a vested interest in perpetuating a bad state of things, and who necessarily detest any Club in any way likely to check their gains. They are, we believe, few, and are certainly not worth any consideration at all. Of the former, however, we should like to say a few words. Some of them have, we fear, a bad opinion of fanciers in general, and despair of this Club or any other being able to effect its object. They consider all its work as so much useless labour, in which they naturally do not wish to take part. There may in the past have been much to justify their gloomy view of the matter, but we think that their mistake is now almost capable of proof. Many more are afraid to commit themselves to any decided action; the Club may probably come into collision with certain exhibitors and managers of shows, with whom they think it more politic to be on good terms; they have not the courage to risk the possibility of giving offence to someone, and above all have a perfect terror of identifying themselves with any movement which has ever been, or is ever likely to be, abused in public print. We will not tax our readers' patience by remonstrating with what seems to us a want of moral courage, though often found in most amiable people and agreeable fanciers. The former class, however, have all our sympathy, and probably that of the Club. For them, doubtless, the circular is chiefly intended, and if any remarks of ours, based on what we can gather concerning the past history of the Club, should have weight with them it will be a source of great satisfaction to us.

At the risk of seeming to tell a thrice-told tale we go back some four years to trace the origin of the Club. Several outrageous cases of prizes being carried off by "trimmed" birds, to the injury of honest exhibitors, were on the lips of every fancier; but apart from and even before this we believe that the flagrant repudiation of their debts by some committees, and the gross mismanagement of some shows by others, had much to do with its formation. One exhibitor who took a prominent part in founding it, and who has ever since been one of its officers, had lately suffered many things. At one show most of his winners were changed for worthless specimens. He was naturally indignant; but when it was found that the lost birds were traced to a place very near the Show, a majority of the Committee refused to prosecute the matter further, and took refuge in general abuse of the sufferer. The same exhibitor accidentally discovered that at another show his best birds were kept in their baskets till the judging was over. He consulted lawyers, but was warned of the great difficulty and immense cost of collecting convincing evidence; in fact, it was seen that in such cases an individual is almost powerless against a body. "What could be done to remedy such a state of things?" It occurred to several fanciers at once to unite themselves in a friendly company, and to subscribe a common fund for mutual protection. The idea was a good one, but while the scheme was in embryo arose a general call for a more extended club, and so the lesser was merged in the greater undertaking. Its main objects then were—1, The suppression of "trimming;" 2, Mutual protection of the members against all such losses and injuries as we have related. The question now is, How far have these objects been carried out? and how far are they in a way to be still further carried out?

To the first question we answer—Read in the report of the Club, which we lately published, the opinion of the late Mr. E. Hewitt, and ask that of some of the best and most experienced judges at the late shows. Intelligent observation will, moreover, convince any person conversant with the matter that as a rule poultry are far more honestly shown than they were four years ago. If, then, there has been already this improvement, still further progress may reasonably be expected.

2. The protection afforded to members is less demonstrable, because for various reasons numbers of cases in which they appeal to the Club are not published. Documents have, however, been put before us which show that never a month passes without some member receiving redress through the Club—aye, and sometimes non-members; for it has been most ungrudging in helping fanciers external to its body. It is not many days since the threat of "disqualification" caused the managers of a show to settle at once,

and to telegraph the settlement of a claim of some standing, all applications for which made by an individual had been disregarded.

For these reasons we hope that all the well-meaning fanciers who have not seen their way to joining the Club will read the circular about to be issued, and, if they see that they are profiting by the work of their brother fanciers, will not hesitate to undertake a part of their burden.—C.

EYMORE BLACK FOWLS.

IN the excellent report of the great poultry Show at Birmingham in last week's Journal I see it is stated fowls of this variety were third in the variety class, and information is sought as to what they really are. This is what many would like to know. If Mr. Gabb the owner cannot say I have no doubt Mr. Burnell the Judge will be able to tell us all about them, as I presume no judge would give any fowls a prize unless he knew what they were, and that they were thoroughly worthy of this distinction. Are they good layers and hardy, easily reared, quick in growth, and good for table?—J. MUIR, *Margam*.

YORK POULTRY AND PIGEON SHOW.

THIS Show opened on the Tuesday of this week, and closes to-night. Poultry had twenty-six classes with 333 entries, and Pigeons seventeen classes with 157 entries. The prizes were from £1 down to 5s. The poultry were in all cases shown in pairs; the Pigeons, as a rule, singly. The arrangements were on the whole good. It was a mistake, however, to put the heavier birds so high up, and the perches might well have been left out of the pens of the larger varieties. The smaller sorts and Bantams seemed to appreciate them. Mr. H. Beldon judged the poultry; Mr. J. Hawley the Pigeons. Mr. B. Kilvington, jun., acted as Steward, and it was chiefly through his promptitude in getting the awards up and courtesy to us, that we are enabled to give our report this week. The catalogue opened with

DORKINGS (seventeen).—Only a moderate class. The winners (Cannan) being rather long in leg, and the cock squirrel-tailed. Second (B. Smith) contained the best hen in the class, but she dwarfed the cockrel her mate. Third (Newall); h.c., Lord, Pounder, B. Smith; c., White.

SPANISH (eight).—First (Rawnsley) a nice pair of chickens, best in quality of face and condition, but rather narrow in lobe. Second (Cannan) an old pair, the cock large but rough in face and going blind, the hen also rather rough in face. Third (Thresh) a good old pair but not in condition; h.c., Doulton.

COCHINS.—*Buff* (fourteen).—A fair average class. First (Croft) a shapely old hen, rather mealy in colour, mated with a medium-sized cock deficient in breast; hocked. Second (Thornton) a fair young pair, hocked again; size and colour moderate. Third (C. Brown) a good pair of lemon chickens, nice in hock, but the cock too long in leg and carrying too much tail; v.h.c. (Mitchell) might have stood higher but for the cock's defective comb; h.c., Rawnsley, Pounder, Barker, Southwell. *Any Other Colour* (fourteen).—A medium class. First (Sowthern) went to a pair of Partridge, both hocked; the cock bright in colour, but too large in tail and wanting in saddle; the hen good in marking. Second (Rawnsley) Whites of fair quality, the hen being the best of the two. Third (Carr) Whites again, the cock with too much tail and a canary shade through his hackles; v.h.c. (Southwell) moderate Blacks; v.h.c., Cannan; h.c., Clayton, Ewbank, Handley.

BRAHMAS.—*Dark* (fifteen).—Taken all round this was a very poor class, some of the exhibits being the worst we have ever seen in a pen: one pair had actually well-developed single combs. The winning pen (W. Mitchell) contained the Hull cup cockerel and a moderately marked pullet of the Kendrick stamp. Second (Eastwood) a fine old cock with too much tail and too little saddle, mated with a small hen heavy in moult, brown in colour, and heavy in head. Third (Holmes) a slim pair of chickens too long in leg; v.h.c., Wilkinson. *Light* (twelve) were better as a class than Darks, but still contained a pen of pure Whites with single combs. First (Cannan) were a good all-round old pair, but that the cock was warm in colour and rather heavy in comb. Second (Williams), the cock neat in head but extremely hollow in breast; both birds very yellow. Third (Hudson) a shapely hen, bad in colour, mated with a cock of similar stamp; h.c., Edwards, Grieve.

HOUDAN or CREVE (eleven).—A fair class. First (Cannan) Crèves, the hen particularly good in crest, muffling, and shape; the cock only moderate in crest, but in good condition. Second (Chadwick) good Crèves again, lighter in build than the winners. Third (Perry) moderate old Houdans.

GAME.—*Black or Brown Reds over one year* (seven).—A very poor class. First (Cannan) moderate Brown Reds, the cock very loose in carriage of wing. Second (Chadwick) and third (Perry) Brown Reds also. *Any other colour over one year* (six).—Another poor class, the only really good pen being the first (Crofts). Second J. Walker, third R. Walker. All three were yellow-legged Piles. *Any colour, hatched in 1880* (seventeen).—A very moderate class. First (Firth) fair Brown Reds. Second, third, and v.h.c. (Thompson) Black Reds.

HAMBURGS.—*Golden-pencilled* (fifteen).—A good class. First (Rawnsley) neat in comb and lobe and good in marking. Second (Kidson) neat in head also, but not so good in colour. Third (Webster), the cock coarser in comb and not so clear in lobe, but rich in colour; h.c., Rawnsley, Digby, Kidson. *Silver-pencilled* (five).—Moderate. First (Rawnsley) a stylish pair, but the cock rather poor in colour. Second (H. Smith), cock rough in comb and very wild, but well marked in tail. Third (Carver) poor in lobe; h.c., Rawnsley. *Golden-spangled* (eleven) contained nothing wonderful. First (Cannan) rich in colour but rough in comb and stained in lobe. Second (Rawnsley) also poor in lobe, and the hen out of sorts. Third, Rawnsley. *Silver-spangled* (fifteen).—A moderate class. First (Cannan) good in marking but rough in comb and bad in lobe; as also were second, Rawnsley; and third, Dodgson; h.c., Rawnsley, Dodgson. *Blacks* (eighteen) seem to be popular here. First (Pemberton) a stylish hen, good in head and lobe, and bright in colour. Second (Rawnsley) good in lobe and colour, but the cock coarse in comb. Third (Digby), the cock bright in colour and good in lobe, but comb crooked; h.c., Rawnsley, Sidgwick, Rutherford, all fairly good; c., Gunn.

POLISH (eight).—A moderate class, both first and second going to Mr. Rawnsley with a pretty pen of Golden rather white in crest, and a good pair of White-crested Blacks; v.h.c. (Cannan) good Silvers hardly in condition; h.c., Perry.

ANY OTHER VARIETY EXCEPT BANTAMS (twelve).—First (Hutchinson) stylish Malays, bright in colour and hard in feather. Second (Rawnsley) neat Sultans, rather short of foot feather. Third (Crewe) Malays again; h.c. (Bellerley), Andalusians; h.c. (Thurgood), Minorcas; h.c. (Anthony), White Leghorns. 321 (Foggin) a pretty pair of Silky Bantams wrongly classed.

GAME BANTAMS.—*Black or Brown Red* (twenty).—A poor class for its numbers. First (Southwell) a very neat pair of Black Reds. Second (Chadwick) moderate Brown Reds. Third (Beckett & Dodson) Black Reds again, as also were h.c., Blakey. *Any Other Colour* (twenty) also only a moderate class. First (Cannan) moderate yellow-legged Piles badly shown. Second (Firth), Piles also willow-legged. Third (Schofield) Duckwings; h.c. (Walsham), Piles; h.c. (Henningfield), Duckwings.

BANTAMS.—*Gold or Silver Laced* (eight).—First and second (Richardson) moderate Golds. Third (Rawnsley) neat Silvers. *Any Other Variety*.—First (Cannan) Black Rosecombs, clear in lobe, and bright in condition. Second (Rawnsley) pretty White Rosecombs, nice in colour; h.c., Rawnsley, Preston, Digby, all Black Rosecombs.

TURKEYS (ten) were a good class, the winners being fine bronze birds. First Garforth. Second Edwards; h.c., Kendall, Dowell, Bulman, Chadwick.

GEESE (twelve).—Also a fine class. The winners (Snell) were large Greys. The second (Cannan) fine Whites; v.h.c., Dodworth (White); h.c., Smith and Sutcliffe (Grey); e., Trousdale (White), Chadwick (Grey).

DUCKS.—*Lylesbury* were a fair class of twelve. First (Seoby). Second (Snell); h.c., Dodsworth, Fentriss. *Rouen* (twenty-one).—A good class containing many birds above the average in quality. First (Garforth). Second (Crofts); h.c., Snell, Stamper, Newton, Kingston, Pounder. *Any Other Variety* (seventeen).—Another good class. First (Chadwick) large upstanding Pekins. Second (Cannan) Mandarins. Third (Gunn) good Pekins again; h.c., Snell, Leng, Crewe (all Pekins).

PIGEONS.

CARRIERS.—*Cock* (six).—A moderate class. First (Robinson) a Black, as also were second; h.c., Gell and c., Booth. *Hen* (six).—First (Gell) a Dun; second (Gell) a Black; c., Bocking.

BARBS.—*Cock* (five).—First and second (Gell) were both Duns; h.c., Thurwell, Fawcett (Blacks). *Hen* (three).—First (Gell) a Dun; second (Thresh) a Yellow; h.c., Gell (Black).

POUTER (six).—First (Robinson) a Blue-pied; second (Crofts) a Black-pied; v.h.c. (Robinson) a Dun-pied; h.c., Harrison, Lund, both Blue-pied.

TUMBLER.—*Almond* (five).—First and second (Weston) were good in head, but not first-class in colour; h.c., Robinson, Martin (2). *Short-faced, any other variety* (ten).—First (Martin) a Red Agate; second (Martin) a Silver; h.c., Weston (2, Blacks), Robinson.

TURBITS.—*Blue or Silver* (eight).—First (H. Robinson) and second (Goldsborough) were both of the first-named colour; h.c., A. Robinson, Cass. *Any Other Colour* (eight).—First and second (Parkin) a Yellow and a Dun; h.c., A. Robinson, Crofts.

OWLS (eleven).—First and second (Thresh) both Blue English; h.c., R. Rawnsley, J. W. Robinson, Weston.

FANTAILS (ten) were all Whites. First A. Robinson; second Loversidge; h.c., Lawson; c., Crofts.

JACOBINS (twelve).—First (J. W. Robinson) a Red. Second (Bocking) a Yellow; h.c., Cass (a Red); e., Robinson, Bocking.

NUNS (sixteen).—First (Horsley) a Black, as also we think was second (Stanley); h.c., Cass, J. W. Robinson (2), J. B. Rawnsley; c., W. H. Fowler.

DRAGOONS (twenty).—First (Shewell) a Blue, as also was second (Tate & Ewen); h.c., ditto; e., Benson, Close.

ANTWERPS (twenty-one) were a good class, first and second going to Mr. B. Rawnsley. h.c., Scurr; e., Armstrong, Ward.

TURTLE DOVES, pair (four), were all fair specimens. First (Eastwood) were Ringdoves; second (Ringrose) Whites; h.c., Ringrose; e., Eastwood.

ANY OTHER VARIETY OF PIGEON closed the catalogue with seven entries.—First (A. Robinson) were good Trumpeters. Second (Abell) Wood Pigeons. Third (Harrison) Red Magpies.

KINGSTON-ON-THAMES POULTRY SHOW.

WE attended this Show, which was held on the 2nd, 3rd, and 4th inst., prepared to make a note merely of the leading birds, but we found the exhibits in nearly all the classes so numerous and good in quality that we thought it best to give the full list of awards. Poultry numbered 360 entries without counting the Selling classes, and were divided into thirty-one classes with four prizes in each. They had ten cups, and the Pigeons a similar number. The building (a drill hall) in which the Show was held is spacious, but hardly light enough in some parts. The general management and feeding were excellent. Mr. T. C. Burnell judged the poultry, and Mr. P. H. Jones the Pigeons.

DORKINGS.—*Coloured* (eleven).—First (Warren) a good all-round pair, as were also second (Newick). Third (Rigg) moderate chickens. Fourth (Radclyffe) fair old birds. *Whites* (nine).—The first (Woodgate) also took the Dorking cup. They were best as a pair, and, indeed, of considerable merit. The hen in the second (Pilgrim) pen was grand in size and shape for a White, but her mate was not her equal. Third (Logan) a moderate pen. Fourth (Browne) a good hen, but the cock coarse in comb. *Any other colour* (six).—First (Radclyffe) a large shapely pair of Silver-Greys. Second (Virgo) rather dark single-combed Cuckoos. Third (Haddock) moderate Silver-Greys. Fourth (Clark) fair rose-combed Cuckoos.

COCHINS.—*Partridge or Buffs* (nineteen).—First-and-cup (Jenkins) a large evenly coloured pair of Buffs of the light shade. Second (Turner) a very good pair of Partridge, the hen specially well marked. Third (C. Brown) nice Buffs again, hocked. Fourth (G. H. Wood) another good pair of Partridge. *Any other colour* (nine).—First (G. H. Wood) Whites, the hen especially being good in size and shape. Second (Thompson) moderate Whites. Third (Turner) middling Blacks. Fourth (Metcalf) good Whites again.

BRAHMAS.—*Dark* (thirteen).—A very moderate class. First-and-cup (Norris) a good old pair, the cock rather coarse in comb; the hen well marked on breast and very good in shape, but wanting in body marking and short of foot feather. Second Tindall, third Turner, fourth Metcalfe. *Lights* (ten).—First (G. H. Wood) a very good pen, the hen rather soft in cushion. Second (Thurlo) had both far too much tail. Third (Wells) poor in size. Fourth (Turner) both very heavy in head.

GAME.—*Black Reds.*—*Cocks* (twenty) were not a strong class. First-and-cup for cocks (Tyler) neat in head and rich in body colour, but mossy on fluff. Second (Docksey) not so good in colour. Third (Theobald) still worse. Fourth (Docksey) splashed on breast. *Hens* (twenty-five).—First-and-cup for best hen, also cup for best Game bird (Maynard), a stylish hen, good in colour, but flat in shin. Second (Tyler) not so stylish as the winner. Third (Docksey) failing in colour on wing, as also did the fourth (Lewendon). *Brown Reds.*—*Cocks* (ten).—First (Warde) good in head and rakish in style, but not right in colour. Second Mercer, third Rowley; fourth Martin, nicely pencilled on breast. *Hens* (nine).—First (Warde) and second (Martin) both good in style and colour. Third and fourth Mercer. *Duckwings.*—*Cocks* (seven).—First (Hullett) fair shape and colour, but too much hackle; second Martin, third Thomas, fourth Hullett. *Hens* (eight).—First (Lewendon) good in style and colour; second Fenn, third Huxtable, fourth Theobald. *Pile.*—*Cocks* (five).—First (Foster) neat head and good shape, but only moderate colour. Second (Theobald) large and rather heavy. Third and fourth Warde. *Hens* (ten) contained nothing remarkable. First Warde, second Theobald, third Adams, fourth Warde.

SPANISH (four).—First-and-cup (Brown) a very neat pair of chickens, face and lobe of good quality, but not enough of it. Second (Wells) also a good pair, the cock especially being nice in face and lobe, though a trifle rough. Third Nash, fourth Morton.

LEGHORNS (seventeen) a good class. First (Brown) a good all-round pair of Browns. Second (Verrey) Browns again, the cock very coarse in comb and poor in lobe. Third (Bradbury) smart Whites but for the cock's drooping comb. Fourth (Philcox) good Browns.

ANDALUSIANS.—A fair class of sixteen. First (Winner) well pencilled, but cock very large in comb. Second (Winner) moderate only in pencilling. Third (Bacon) a neat nicely pencilled pair. Fourth (Manchif) very dusky.

MINORCAS (thirteen).—First (Harwood) the cock very neat in comb and clear in lobe. Second (Dominy), the cock very heavy in comb. Third (Leat) and fourth (Parkhouse) both smart pairs.

HOUDANS (eight) were a good class. Mr. Howard's well-known pair were to the front again. Second Lane, third Jackson, fourth Hanson. *Any other French* (four).—First (Jackson) fair-sized Crèves, second (Darley) ditto, third withheld, fourth (Ridley) La Flèche.

HAMBURGS.—*Gold or Silver-pencilled* (fourteen).—First (Orriss) pretty Golds, second (Tickner) Golds again, as also were third (Castell) and fourth (Mowlem). In *Spangles* (nine), on the other hand, all four prizes went to fair Silvers, well placed. First Wingfield, second Ashwell, third and fourth Plattin. In *Blacks* (six) first (Bell) were glossy

and neat in head properties; second (Ebbs) good in comb and lobe; third Pointer.

ANY OTHER VARIETY (eighteen).—First (G. Burnell) were a good pair of Malays; second (Broad) good White-crested Polish; third (Ekins) Frizzles.

BANTAMS.—*Black or Brown Red Game* (thirteen).—First (Pilkin) neat Black Reds. Second (Leach) Black Reds again, in grand condition. Third (Morgan) stylish Black Reds. Fourth (Vigers) Brown Reds, rather large. *Pile or Duckwing Game* (eleven).—First-and-cup (Pilkin) a neat pair of Piles; second (Davenport) Duckwings; third (Waters) and fourth (Docksey) Piles again. *Any other variety* (seventeen).—First (Barnes) Black Rose-combs; second (Silvester) Silver-laced; third (Clarke) Cuckoos; fourth (Brett) White Rose-combs.

DUCKS.—*Aylesbury* (nine) contained nothing special. First Hedges, Second Sear, third Harris, fourth Lane. In *Pekins* Mr. Nickolls won first and cup with a fine pair; the drake, however, was crested or ridged on neck. Second (Keele), third (Nichols), and fourth (Winter) were all good specimens. *Any other variety.*—First (Howard) moderate Rouens, second (Woodgate) Black East Indian, third (Nicholls) Rouens again, fourth (Goodman) Muscovy.

PIGEONS had twenty classes and close upon three hundred entries. They opened with

POUTERS (six).—First (Baker) went to a Blue-pied, second (Byford) to a White, third (Theobald) and fourth (Sugden) to Dun-pied.

CARRIERS.—*Black or Dun* (seven).—First-and-cup (Baker), second (Cork), and third (Walker) were of the first-named colour, while fourth (Kempton) was a Dun. *Any other colour* (four).—First (Byford) and third (Baker) were Blues, second (Cox) a White, and fourth (Piper) a Dun pied. *Black or Dun of 1880* numbered no less than twenty-three; first-and-cup (Cox), third (Harvey), and fourth (Savage) being Blacks, and second (Hale) a Dun.

DRAGONS were described by the Judge as specially good classes. *Blue or Silver cocks* (nineteen).—First (Calcutt), third (Smith), and fourth (Close) were Blues, second (Smith) a Silver. *Hens* (eleven).—First (Close), second (Norris), and fourth (Calcutt) were Blues, and third (Winner) a Silver. *Any other coloured cocks* (fourteen).—First-and-cup (Howard) a Blue Chequer, second and third (Leith) a Yellow and a Red, and fourth (Patterson) a Yellow. *Hens.*—First (Leith) and fourth (Pratt) Yellows, second (Close) a Blue Chequer, and third (Howard) a White. *Any colour of 1880* (twenty-four).—First (Lush) third (Patterson), and fourth (Dean) were Blues, and second (Leith) a Red.

TUMBLERS (five).—First (Baker), third and fourth (Rayner) were Almonds, second (Langridge) a Red Agate.

JACOBINS (six).—First (Stanfield), third (Baker), and fourth (Ward) were Reds, second (Stanfield) a Yellow.

OWLS (fourteen).—First-and-cup (Baker) a White African, second and third (Van Senden) a Blue and a Silver, fourth (Stanfield) a Blue.

TURBITS (twelve).—First (Baker) a Red, second (Holmes) a Blue, third (White) a Yellow, and fourth (Cork) a Black.

FANTAILS were only four, and all Whites. First Baker; second and third Bakewell; fourth Hale.

ANTWERPS, Short-faced cocks (nine).—First-and-cup (Turner) and second (Albury) Red Chequers, third and fourth (Theobald) a Silver and a Blue. *Short-faced hens* (eleven).—First (Jefferies), second (Albury), third (Buckland), and fourth (Wearing) were all Red Chequers. *Homing cocks* numbered no less than forty-nine. First-and-cup (Jenkinson) a Blue Chequer, second (Herrieff) a Silver Dun, third (Browne) a Blue Chequer, and fourth (Leake) a Red Chequer.

Hens (forty).—We did not note the colours of the winners, but have an impression that they were mostly Red Chequers. First Browne, second Winner, third Sayers, and fourth Key.

ANY OTHER VARIETY (eight).—First and second Baker, third Allen, and fourth Lamb.

THE BIRMINGHAM SHOW.

IN our report of this Show last week we omitted one or two matters which may be of interest to our readers. The first was the protest against Mr. Norris's Dark Brahma pullet as being an old hen (lodged by Mr. Percival's poultryman); the omission was intentional upon our part, as we had not received any intimation of the decision of the Council before going to press. We have since learned that the Council considered Mr. Norris's explanation perfectly satisfactory, and held that the decision of such a matter as that of the age of a bird rested entirely with the Judge. We see no reason to believe that Mr. Norris's pullet was over the specified age. The fact that she has been exhibited under no less than five judges, and in the first instance as early as September, seems a conclusive answer to any objection on this score. We may mention that at the Show there was a great deal of discussion amongst certain individuals as to both the age of Mr. Norris's pullet and the tail of his third-prize cock in the Dark Brahma class. We think it extremely reprehensible in such cases to call the honesty of an exhibitor into question without good evidence, and if there be good evidence the hostile comments should in every case be followed by a protest. If there be not evidence those doubting the honesty of the exhibitor should, in our view, keep their opinions to themselves, and not blazon them abroad through a show to the detriment of the person directly interested, and to the degradation of the fancy generally.

Another matter upon which we should have wished to say a few words was a new incubator brought forward by Mr. Tomlinson. In

the pressure upon our time caused by the necessity of our going so early to press we had merely time to take a casual glance at this incubator. We hope before very long, however, to have an opportunity of examining it in detail, and giving our readers the particulars.

In the class for Buff Cochins the first prize and cup was won by Mr. Procter, and not by Mr. Tomlinson, as inadvertently published in our report.

In our last issue we perhaps hardly sufficiently acknowledged the general excellence of the management and the great improvement in many points effected this year both in regard to penning, arrangement of pens, and feeding. Everything was thoroughly well done, and we congratulate the management upon their success.

Our comments upon the various classes will have sufficiently indicated to our readers our general views as to the judging; but in one case—that of Mr. Leno—we desire to say an extra word of recognition. He is comparatively a new hand at the Brahmas—sufficiently tough subjects for adjudication—and his awards in the classes upon which he adjudicated were, as far as we could learn, accepted with entire approbation. That it should have been so speaks well for the manner in which he discharged his difficult duty.

VARIETIES.

THE ROYAL AGRICULTURAL SOCIETY.—At the last meeting of the Council the Hon. W. Egerton, as Chairman of the Veterinary Committee, brought up a report in which it was stated that foot-and-mouth disease was still on the increase. They had reason to believe that the disease has been introduced by French cattle into Deptford Market, and they recommended that the Privy Council be urged to take additional precautions to prevent the spread of contagious diseases from that market. Mr. Chas. Whitehead, on behalf of the Seeds Committee, reported in favour of withholding the prizes offered for new varieties of Wheat, as the competitors had not satisfactorily proved that the Wheats entered by them were distinctly new varieties. On the motion of Mr. Dent it was decided to set aside a sum of £500 for educational work during the ensuing year; and on the motion of the Hon. W. Egerton the Council made a grant of £250 to be expended in veterinary investigations. Various standing Committees were appointed, and some business in reference to next year's Show at Derby was transacted. Mr. Jacob Wilson was re-elected Steward of general arrangements at the Society's Shows for a term of three years.

— PRESERVED AUSTRALIAN RABBITS.—The Australian Meat Preserving Companies, which have during the last year or two taken to cooking and "preserving" rabbits which have been killed in such enormous numbers, have found their resources unequal to the task of boiling and tinning in a fresh state all the rabbits which have been offered to them. The Colac Preserving Company, for instance, whose works are situated about ninety miles from Melbourne, had on an average 7000 of these rodents brought in every night for the first four nights of the past season's operations. How the supply would have increased as the season advanced it is impossible to say, but orders were given to limit the daily quantity to 2700 pairs. This number cooked and "canned" for five days a week and during a season of twenty-five weeks gave 675,000 rabbits as the return for one establishment—a quantity which is 50 per cent. more than was dealt with in the season of 1879.

— THE MILK TRADE.—At the sixth anniversary dinner of the Metropolitan Dairymen's Benevolent Association, which was founded in 1874 for the relief of aged and infirm members of the trade and their widows, and which is supported by voluntary contributions, the Chairman said that there were no less than four million cows kept in this country, and the value of that stock was worth seventy millions of money. In addition to that, dairy produce was yearly imported to the value of fourteen millions of money. The trade was growing and increasing in importance, and the yearly growth of the population in this country required an annual increase of sixty thousand cows to meet the wants of dairy produce. He incidentally referred to the foreign importation of milk, and said the Privy Council should prohibit the bringing into this country of that commodity from places where the foot-and-mouth disease was known to exist, as there was danger of its breaking out here.

— AGRICULTURE IN IRELAND.—The Royal Agricultural Society finds some difficulty in getting a place for its Show of 1881. Mullingar has been spoken of, and a member of the Local Committee

attended the monthly meeting of the Council in Dublin, and stated that the subscriptions promised amounted only to £840. The opinion was expressed that less than £2000 would be insufficient. It was stated that under ordinary circumstances there would have been no difficulty in getting the requisite amount subscribed. The Chairman said if the Show was not held in Mullingar there would be no Show at all next year. It was ultimately resolved to postpone the decision for two months, to give time for getting further subscriptions. The Show is usually fixed four months before this period of the year. Mr. Rochefort Boyd, D.L., stated that the rents in the centre of Ireland were being remarkably well paid, and that the landlords of that part of the country had no excuse for not coming forward and subscribing towards the expense of holding the Society's show next year at Mullingar.

— PROPOSED BRISTOL CHANNEL OBSERVATORY.—Mr. E. J. Lowe, F.R.S., who for the last forty years has carried on a regular series of meteorological observations at Highfield, near Nottingham, has recently purchased the Shirenewton estate, near Chepstow; and, being convinced of the real importance of establishing an observatory which may be carried on through future years without interruption, has generously offered to present the whole of his valuable collection of meteorological instruments, together with his books and papers, towards the establishment of such a permanent observatory, for which he also offers to give the site, together with such stone and lime as may be required for the erection of the necessary buildings, provided a sufficient sum can be raised in the district to build the same, and to provide a small endowment towards the maintenance of a limited staff of assistants, who would in the first instance be under his gratuitous guidance and supervision. Mr. Lowe, if his offer is accepted, proposes to vest the property in the following trustees:—The Duke of Beaufort, the Marquis of Bute, the Duke of Somerset the Earl of Cork and Orrery, the Earl of Cawdor, the Earl of Ducie, Lord Kensington, M.P.; Lord Tredegar; C. R. M. Talbot, Esq., M.P.; Sir W. V. Guise, Bart.; Sir John Lubbock, Bart., M.P.; Sir John Maclean; J. A. Rolls, Esq., M.P.; S. S. Marling, Esq., M.P.; Samuel Morley, Esq., M.P.; Christopher J. Thomas, Esq.; and W. R. Edwards, Esq.

— AMERICAN DAIRY CATTLE.—The Shorthorns are largely in excess of all other pure bloods in the United States; and although their influence is felt mainly in the improvement of beef cattle, many dairymen hold them in high favour. Mr. Harris Lewis, one of the best known dairymen of New York, writes:—"There is no way known to me by which our dairymen can so easily and certainly improve the milking qualities of our native herds as by using a thoroughbred Shorthorn bull, and raising the heifer calves of the best milkers. The bull should be from a good milking family of Shorthorns. I commenced this practice several years ago, and the result has been so favourable to the Durhams that I am now running into the thoroughbreds for my dairy. The first cross of the native cow with a Shorthorn bull usually produces better results than subsequent crosses, but this rule may not hold good if the bulls used for the second or third crosses are of superior milking stock to the one first used. I find that our Herkimer County dairymen, with all their prejudices against Durhams as milkers, will first select from droves of cows brought in for sale the Shorthorn grades, and pay better prices for them than for superior natives."—(From "*Dairy Farming*," by Professor Sheldon, for December.)

HINTS FOR THE SAFE WINTERING OF BEES.

REPETITION of oft-given instructions needs no apology in the particular case of bee-keeping, because from the peculiarity of their management the wants of bees are very apt to be overlooked. It is only for three or four months in the year that the cares of the apiary are engrossing. Active interest from day to day in the progress of each hive lasts only from May to August inclusive in most apiaries in the kingdom. The rest of the year is, in comparison, a dull and dreary time with little to interest the bee-keeper; therefore he is apt to forget his bees and so to neglect them—not intentionally, but other matters press upon his attention, till he finds, too often to his chagrin and loss, that mischief has been going on among his hives past remedy.

Let me, therefore, summarise what it will be important to attend to ere it be too late. 1, As to food. This is obviously of the first necessity, to see that every hive has enough and to spare. We have had some very warm days this autumn, and even a continuance of them. Breeding, therefore, has been in unusually active operation, and consequently much stored honey has already been consumed. Where there is the slightest suspicion of a possible lack of food it must be supplied forthwith. Choose the warmest days which may be given us, and top feed in small quantities, when the sun is out and the air calm. Remove the feeders and cover up the holes some time before sunset. In extreme cases it is a good plan to close the entrances and to bring the hives into the house at night, when they may be fed for some hours by the fireside in the warm kitchen; also, barleysugar may be given them both at top and bottom where it is not convenient to feed in any other way. If syrup is the food supplied it should now be somewhat thick and fortified with a little gin or other spirit. The sooner this is done the better; but beware of feeding when the temperature is low or the wind high if the bees have access to the open air.

2, Protection is the next important matter to be attended to. Already we have had the before-cast shadows of coming events in the snows and severe frosts which have visited us this year so much earlier than usual. Therefore let all bee-keepers look well to their hives, and see that no damp from snow or rain can lurk or linger about them.

3, Hive entrances should be narrowed and guarded carefully against intrusion of mice or other vermin. If possible during the coldest weather, when snow lies deep or high winds prevail, and even in the treacherous weather of advancing spring, it will be often advisable to close the entrances altogether. Perforated zinc blocks will be found useful for this purpose, such as can easily be removed and replaced. Remove them on all soft sunny days, replacing them when the evening comes, and by their means keeping the bees confined in all uncertain or rough and stormy weather. By this means many a valuable life will be saved. Bees can be kept thus at home for several days together without much, if any, serious inconvenience to themselves. This treatment can be prolonged quite to the middle of April in the case of all but the most forward stock. But when once the population begins to extend itself so as to cover three parts of the combs it will no longer be prudent to confine the bees; nor should this ever be done without seeing to the due ventilation of the stock by the application of bits of perforated zinc at the entrance and over the hole or holes at the top of the hive.

4, Pedestals should be examined, and new and strong supports given wherever there is the least suspicion of decay, otherwise some stormy day the hives will be found overturned and ruined by some sudden gust of wind.

5, Now is the time also for making all preparations for the future season. New hives should be made, and old and worn-out hives destroyed, especially if there is any suspicion of lurking disease, or if the wax moth has got hold of any.

6, If any hives require to be removed in winter, perhaps the best time is just after a long frost. But even then it will not be safe to remove them to any position near their old stand. Nor should they be liberated after their removal till some morning warm and still. If a little syrup (a dessert-spoonful at a time) is poured into the hive at the time of their liberation it will cause an excitement about the hive entrance, which will attract home again any bees which might perhaps otherwise be lost. But I do not advise removing hives at any time of the year except to a considerable distance unless necessity requires it. It is better to wait till swarming time, when special facilities are afforded.—B. & W.

APIARIAN EXHIBITIONS.

I SHOULD like to see a limit to the number of sections and bottles at exhibitions in their classes, say to a dozen each. What chance has a poor cottager at a distance from the show with a rich neighbour? The expense of packing, carriage, &c., entirely excludes the poor man from competition.

Straw skeps should be more encouraged. The majority of cottagers are not yet sufficiently skilful to manage moveable comb hives successfully, but where that skill is forthcoming by all means use moveable combs, as undoubtedly that is the best system.

Transferring the combs from skeps to bar-frames should be either discontinued or done in a business-like manner. Some that were at the St. Albans Show had to be done again after coming out of the tent! What the Judges could think of it I know not, but if I had been judge I should certainly have dis-

qualified them. Transferring, in my mind, should be rendered complete ready for the bees to finish.—STINGER.

BEES IN NOTTINGHAMSHIRE.

IN 1879 I did not obtain an ounce of honey, but was £3 on the wrong side for sugar instead. I had five stocks this spring, one of which died. With swarms from the four, and four stocks I bought cheap in the summer, I raised the number to twelve. I broke ten skeps up, half of them large Pettigrews, took the honey, transferred brood and best combs to frame hives, united, and fed up for the winter. Out of the ten skeps I took 65 lbs. of honey. Paid for sugar £4 1s. Altogether I am about £6 out of pocket this season. I started three years ago, and have lost £16. The only consolation I have are my nine stocks, which, if next season is like the past has been, will cost me a trifle more. I have six frame hives with bees in, the others are skeps. I made the frame hives myself at a cost of about 2s. 6d. each. I can count thirty hives around me which have not 30 lbs. of food amongst them. Last winter killed nineteen out of every twenty colonies kept here on the old style. The coming winter will finish the rest if they are not fed, which many bee-keepers refuse to do, except by a handful of sugar on a plate.—NORTH NOTTS.

THE DALBEATTIE BAR-FRAME HIVE.

IN answer to Mr. M. H. Matthews in your issue of November 18th I annex a description of the hive with which I manipulate. After a number of years' improvements with the assistance of Mr. R. Wilson, who is a joiner and a bee-keeper, and the sole maker of the hive, we have found this to be the most efficient combined with cheapness and simplicity of any of the various bar-frame hives of our experience. The body of the hive is 24 inches long by 20 wide, and is double walled up to the level of the frames with a dead air space between. The upper part of the walls is single and hinged, so as to fall down to the level of the frames, which gives easy access to the apiarist when manipulating with the hive, and is of great convenience when closed for receiving hay or chaff cushions in winter. The hinged doors at the ends are constructed to fall down without having to remove the roof, so that easy inspection of the hive can be made. The floor board is moveable, is wedged up in front, and projects 2½ inches along the whole front to form a convenient alighting board. A swarming box with dividing boards is made to take the place of the floor board when inserting a new swarm. The hive has two entrance holes with regulating slides. The holes are 4 inches long, one for brood chamber and the other for supering. The latter is covered with queen-proof zinc, and the whole protected by an ornamental porch, which gives a neat appearance to the hive. The roof is of neat design, 8 inches high at the centre, and along with folding side walls allows 12 inches supering room. The inside of the hive contains thirteen self-adjusting bar-frames 14½ inches by 9 inches, with top bars 17 inches long, resting on zinc edging to prevent the bees from propolis, and so allow the operator to slide or remove the frames with the greatest ease. It has two moveable glass ends and one zinc queen-excluder, which, placed at the centre of the hive, confines the queen to a restricted brood chamber. The openings between the top bars are covered with notched reversible slips, which are useful in top supering.

When placing the hive in winter form we restrict the bees to a certain number of frames according to the strength of the stock, and substitute wooden dummies for glass ends, filling up the vacant space with meadow hay, which keeps them at an equal temperature and allows thorough ventilation.—JOHN THOMSON, 102, High Street, Dalbeattie.

P.S.—A frame containing six one-pound sections is sent out with every hive, which can be inserted instead of ordinary frames.

BEES ON THE MOORS.

HEATHER is known to be rich pasture for bees at a late season, and wherever it is within easy distance of advanced bee-keepers seeking profit their bees are taken to it in August. I am sorry I cannot tell your Leicester correspondent, "C. F." (page 452) how far he is from good fields of Heather. We are twenty-five miles from good Heather, and our bees are, generally speaking, taken to it. "C. F.'s" idea of spending his holidays with his bees among the Heather is a good one. One of our Sale grocers annually spends his holidays at a fashionable watering place. I met him on his return home about two months ago, full of satisfaction and bright with health, and he said he had £9 more money in his pocket than he had when he went. On being asked how he managed this, he said he bred a lot of pug dogs and took them

with him and sold them. If your correspondent could take eight or ten large strong hives on the moors he would return a richer man, and consider that his holiday there was as pleasant as it was profitable.

The gains on the Scotch moors this year were unusually large. The weather was remarkably fine, the hives were well stored with workers, and the combs were not very well filled with honey. Probably the brood of the hives was well advanced and did not require nursing. Under such circumstances large strong stocks have been known to gather from 7 to 10 lbs. each per day, on both Clover and Heather; but 20 lbs. per week per hive is considered good and satisfactory work. It should be remembered that the weight gained by a hive is not a fair measure of the work done by the bees. Their own keep should be taken into consideration. When the Heather blossoms fail, or when weather prevents the bees from working, strong stocks lose in weight more than a pound a day. When honey is being gathered very fast the work inside the hives often gets into arrears, and this accumulation of work occupies the bees some days after the glut of honey has past. Hence the great consumption of honey for awhile after a great gathering.

The honey season of 1880 in Scotland does not fairly settle the question of the superiority of the swarming system of management over the non-swarming. The season until August was a comparative failure. The swarms gathered honey enough to fill their hives with comb and brood, and probably hives that never swarmed at all had no more workers in them at the harvest season than mother hives and their swarms. If the glut of honey had come a month or six weeks sooner and the Heather had been a failure the non-swarming system would have appeared to advantage.—A. PETTIGREW.

OUR LETTER BOX.

Address (Mrs. Horsley).—The address you require is Mr. Edwin Crook, 5, Carnaby Street, Regent Street, London.

Chickens Dying (E. C. G.).—Your birds require more nourishing and more easily digestible food. Very early in the morning give them warm soft food—barley or oatmeal, or pollard mixed with pot liquor or milk, and if a few kitchen scraps are added all the better. The whole should be mixed together, only sufficient liquid being added to form a rather dry crumbling paste. As much of this food should be given to them as they will eat readily. Give kitchen scraps and a little corn at mid-day, and a good feed of sound, not inferior, whole grain at night. Green food should also be supplied to them daily. There is little or no nutriment in the "tail" Barley you are giving to them, and hence they are starving with their crops full. Spratt's food given occasionally would also be beneficial.

Feeding Fowls (Old Subscriber).—Poultry may be fed with horse Beans cracked, but we should prefer to give bean or maize meal mixed with minced vegetables, either Carrots or Cabbage.

Crooked Combs (A Beginner).—We advise you to leave your combs as they are till April, then carefully cut away all the excrescences and irregularities you speak of from such combs as are not occupied with brood. Supply some bar-frames with straight comb between every doctored comb. If your hives swarm you can examine the combs again, and remove or re-arrange them till all are regular. The "solid mass" should be entirely removed as early as possible. The deeper cells will be reduced to their proper size by the bees themselves when they are wanted for brood. You need not meddle with them at all. Your arrangements for ventilation are quite sufficient, but as the weather gets warmer remove some of the pieces of carpet.

Feeding Bees During Winter (A Novice).—Stocks should by the middle of October be provided with food sufficient to carry them through, with a margin, to the early part of March, and during the intervening period all disturbance should be absolutely avoided except where some error in management has rendered it imperatively necessary.

Wintering Transferred Bees (Idem).—Stocks transferred last autumn should be confined by a division board to just so much of their hive as they are able to fill, as hives half empty of comb if left open to the full extent are much against the bees during winter. The great loss of heat this causes involves an increased consumption of stores and reduces the vitality of the whole, even, it may be, fatally. Protect the bees above by a quilt, over which place a bottomless and lidless box 3 or 4 inches deep and the size of the part of the hive to which the bees are confined. Fill this box with chaff, when you may assure yourself of its advantage by passing your hand through the latter on to the quilt, which you will find even during the coldest weather to be really warm. It is a matter of choice whether you transfer next spring before or after swarming. We should transfer early, say the beginning of April, because the bees can be more easily helped in the frame hive than the skep.

How to Divide a Stock in a Frame Hive (Idem).—You could increase your stocks "by taking a sheet of brood and a few bees with it and placing it in another hive, afterwards adding to it a bought queen;" but the plan would be very unphilosophical, as our explanation will show. If you so add the queen the stranger will be given to a mass of old bees, which are only persuaded with great difficulty to receive an alien mother, and in addition, should they start comb-building while they are unwilling to adopt the queen offered them in a cage, the comb made will be of drone size. We recommend you to proceed thus:—Find, on a fine day when the bees are in full flight, the queen in your frame hive, and lift out the comb of brood with the adherent bees and queen and place it in a new hive, which must now be stood upon the old stand, while the old hive must go, of course, to some new station. The bees in flight—i.e., the older bees—will return to their known position, and will thus make a swarm, and will commence to build worker comb to accommodate the eggs the mother is ready to lay. Now add to the old hive the bought queen in a cage. The youngsters not yet old enough to fly will quickly accept her, and brood hatching out will quickly put the stock into condition. The frames must be drawn

together to fill up the space from which the comb was removed; but as soon as the queen is really accepted and the hive appears strong a sheet of foundation may be placed here, and this will be quickly converted into comb. Similarly a sheet of foundation on each side of comb with the made swarm will be of great help. A caution here is necessary. No more certain precursor of loss and disappointment can exist than an over-anxiety to increase stocks in number. Never attempt dividing colonies until they are so strong as to show that swarming is not likely to be long delayed.

Nubian Goats (Old Subscriber).—We are not aware at what price some of the best bred Nubian hornless Goats can be obtained. They will commence breeding and giving milk at from eighteen months to two years old, and they have been known to continue in milk for two years without breeding again, Mr. Dickens' stock especially; his address is 5, Hornsey Street, Holloway Road, London. We are not able to recommend any breeder in particular, but in giving the names of the prizewinners in the class for hornless goats animals may no doubt be obtained from some of these exhibitors, and the stock no doubt are Nubian or having a cross of Nubian blood in them. An application to either of the prizewinners will no doubt be quite sufficient to obtain good animals at a fair price, and every information which may be required concerning their capabilities for milking.—Metropolitan Dairy Show, October, 1880, Class 27, female Goats, long or short-haired, without horns, over two years old. First prize, Mr. J. Arnold, Union Lodge, Liverpool Road, N.; second and very highly commended, Mr. W. Chapman, 7, Compton Place, Canonbury; third, Mr. J. Weston, 49, Arthur Street, King's Road, Chelsea. Commended, Mr. J. H. Bayley, 29½, Great Sutton Street, Clerkenwell. Highly commended, Baroness Burdett-Coutts.

Dairy Management and Food for Cows (R. H. H.).—In reply to your questions, "What is the best book or guide for the management of a dairy? the best food for the cows? to give the largest quantity of milk, &c.?" we can only refer you to the information given in this Journal on the 11th, 18th, and 25th of April, 1878, under the heading, "Management of a Butter-making Dairy." The notes were contributed as the result of a lifetime of experience, giving at the same time all the latest improvements in the management of dairy cattle, &c.

REMARKS.

28th.—Fair with sunshine, calm and mild; starlight evening.
29th.—Fair, damp, and mild; windy in forenoon.
30th.—Morning fine with sunshine; afternoon misty and damp.
1st.—Fair and calm, rain at 9 P.M.
2nd.—Sunshine in forenoon; very damp afternoon; thick fog in evening.
3rd.—Foggy morning, generally cloudy and damp.
4th.—Fair, damp, and mild.
Barometer high, and temperature also considerably above the average.—G. J. SYMONS.

COVENT GARDEN MARKET.—DECEMBER 8.

THERE is very little to quote about supply and demand just now, our market remaining very stationary. Large arrivals of American Apples are still to hand, as also St. Michael Pines. A small consignment of Pears from California has reached us this week.

HOW TO GROW ASPARAGUS.

THERE can be no doubt of the importance and value of Asparagus as a vegetable, but in some soils there is, perhaps, no crop more difficult to establish satisfactorily. In some places it succeeds remarkably well, grows vigorously, and lasts in good condition for many years. As a rule it thrives in gardens situated near the sea-coast if the soil is light and sandy; but when of a tenacious character it is totally unfit for the production of good Asparagus, and to attempt its growth is almost useless without special preparation. To accomplish this will cause much labour in clearing out the soil where it is intended to have the beds, for adding abundance of manure to such heavy soil is one of the greatest mistakes that can be made.

The ground where Asparagus is to be grown should always be well drained: if drainage is deficient the roots soon perish and die during winter, but if well drained it is unnecessary to place under the beds clinkers or broken bricks. Before taking out the soil where it is proposed to plant the Asparagus a good fire should be started, if convenient, to burn a portion of the soil as it is taken out, which can again be worked in with advantage amongst the compost intended to be used. Nothing better will be found for this purpose than old potting soil, and it matters but little if quantities of crocks remain amongst the soil. Prunings and material from the rubbish heap should also be burned and mixed with a good quantity of partially decayed leaves; this with a moderate amount of manure will be suitable for the beds. A few loads of coarse river or sea sand can be advantageously employed according to the lightness of the soil. Road sweepings are excellent for this purpose, as they frequently contain coarse sand or small gravel, leaves, horse droppings, and other manures. The materials should be well mixed together and wheeled into the beds; a heavy dressing of hot lime should then be given, and the whole mass well trenched so as to thoroughly incorporate the natural soil remaining underneath with the lime and other mixture. This can be prepared any time during the winter so as to be ready in the spring.

The best time for planting, according to my experience, is when the plants are commencing growth. Purchased plants I do not like, and I would prefer sowing seed in April. The reason I object to purchased plants, especially if they come from a distance, is because they are dried too much in transit. A number of beds can be prepared and the seed sown, from which plants can be obtained the following spring for other beds, or the seedlings can be thinned out to the necessary

distance. When growth has commenced lift the plants in small bunches without shaking off the soil. I do not see the advantage of splitting them up and planting single crowns. A line should be drawn and a trench made so that the roots can be spread out and then covered at once, placing about an inch depth of soil above the crowns, and when the planting is completed slightly cover the bed with short dung and decayed leaves. If planted deeply at first the crowns soon, by constant top-dressings, become too deep. The Asparagus here has been hitherto planted in beds, but I do not recommend the system. I cannot see any advantage in having it in beds, as much labour is caused in keeping them neat. When in beds, if the plants grow luxuriantly they not unfrequently become too crowded and have not room to thoroughly develop. If planted in rows 18 inches apart and 1 foot or 14 inches from plant to plant, ample space is allowed to work any short manure in with a fork in spring. After the foliage has died and been cleared off, the beds should be well covered with fresh manure. Care must be taken that this operation is done before frosty weather sets in; for although Asparagus is hardy when established, I believe many young plants are killed in winter by frost, especially if the ground be wet.

While growing liberal applications of liquid manure, especially during dry weather in summer, are very beneficial. Guano acts quickly if strewn over the beds during showery weather. Asparagus is benefited by slight applications of salt; and if seaweed can be obtained it may be laid over the beds in autumn instead of the manure: no salt is then required. It is often very difficult to obtain seaweed when situated some distance inland; however, salt can be used, but it should be employed carefully, or it will do more harm than good. Salt can be applied in spring as growth commences, which is doubtless the best time. When it is used in quantity during the autumn and winter it tends to keep the soil too wet.

To many readers of the *Journal* the practice indicated may appear to entail a good deal of labour, and especially to those who have suitable soil in which Asparagus will do well with scarcely any preparation, as I have seen in previous years. In those days I should have thought it needless to be at the trouble I have detailed in growing this crop; but in the garden here I found five beds from which I could not cut one dish. The particulars given have been carried out except wheeling out the soil where the Asparagus is planted. The ground was low to start with, and without wheeling any away I had to add abundance of the fresh compost to make it level with the other portion of the garden. There can be no doubt that burnt soil and rubbish is admirably adapted for mixing with soil for Asparagus beds. I had collected all summer and autumn grass from the lawns, prunings, edgings from the sides of walks, rough leaves, and small branches from amongst the shrubberies—in fact, all kinds of rubbish that would burn; and by the end of the season I had a valuable heap of ashes and old soil, as well as abundance of old leaf soil and sweepings from the lawns. I have now full and good beds of Asparagus. When old potting soil and garden rubbish prove to be of value for growing this as well as other kitchen garden crops, as recorded by Messrs. Record and Iggulden, who would grudge the time and labour required in saving and preparing it if such advantages are to be gained?

—WM. BARDNEY.

ON page 503 Mr. Nunns gives his experience with Asparagus,

which, to say the least, has been most discouraging and unfortunate. As he remarks at the commencement of his commendable confession of failure, "Asparagus is one of the most important vegetables grown in the kitchen garden;" and therefore the comments by different growers, if they do not exactly afford the true cause of Mr. Nunns' failure, may yet prove instructive to many readers of this Journal. It seems to me that your correspondent, although he appears to have gone earnestly to work, has really killed his plants with kindness. A perusal of his notes gives the impression that he has employed by far too much manure for almost any soil, and especially a "stiff retentive loam." What may prove quite proper for a sandy loam or light soil, with, say, a gravelly subsoil, which is naturally drained quickly, may be altogether unsuited for a heavy retentive soil, the subsoil of which is generally somewhat in keeping with that on the surface. According to your correspondent's showing the piece of ground selected "was rather wet," and the probability is that the garden is imperfectly drained. Unfortunately he is not so explicit on this point as in others. Drained no doubt the garden is, but at what depth? and how far apart are the drains? From the fact of the surface being rather wet I should surmise that the drains are too deep to act properly, as there is no doubt that unbroken shale is almost impervious to water. In a plantation here, for instance, I found some deep drains quite useless, nothing short of shallow open drains being of avail. The subsoil I found comparatively dry when taking out a large Conifer, whereas the surface soil had to be washed off the spades repeatedly. The hole made by taking out the tree was enlarged, surface drains were cut to it, and it has ever since been nearly full of water. This, of course, is an exceptional case, but I quote it to demonstrate the necessity of having shallow drains in some soils. In the same garden in which Asparagus failed, most vegetables, Strawberries, Peaches and Nectarines, Apples and Pears, all succeed well. But the question is, Was the ground trenched for them with great quantities of manure worked in to a good depth, causing the roots to extend so far downwards as to be destroyed owing to excessive moisture? which I consider the true cause of the Asparagus failure.

Had I the management of such a garden not much of the shale would find its way to the surface, at all events till its character had been much changed. Instead of the drains being, as usual, $1\frac{1}{2}$ rod apart and from 3 to 4 feet in depth, they should be only 1 rod apart and 2 feet in depth. The drainage pipes should be covered with broken bricks, clinkers, or other rough lasting material 6 inches in depth, and the shale be broken up to the level of this, working in as much refuse as is obtainable, and other undecayed material. The top spit of stiff retentive loam I should endeavour to improve by digging it up very roughly in the autumn, occasionally employing a dressing of quicklime, and as much leaf soil and spent tan, cocoa-nut fibre refuse, ashes, decayed garden refuse, road trimmings, and anything suitable that could be obtained, the aim being to provide a sufficiency of good workable soil without trenching deeply.

To break up and work many kinds of soil, under the impression that the land is better drained thereby, is a great mistake, as in reality the more it is broken up the more sodden it becomes, and in which state it will remain for a long time. Rather than plant or sow on a great depth of saturated soil, I would much prefer having ground freshly dug one spit in depth. Here, for instance, we seldom dig for many early crops till a few hours prior to planting or sowing, as the case may be, taking care as much as possible to select a dry time for the operation, even if we wait a few days over the regulation time. Once our soil becomes saturated, the greatest difficulty is experienced in having it dry to a sufficient depth, especially during the spring months. No after labour will compensate for planting when the ground is unfit.

With regard to Asparagus the question is, Does it require such elaborate preparations as are usually made for it? I say, Certainly not. If instead of making deep rich beds—(which in Mr. Nunns' case, were cut out of a hard subsoil, thereby probably forming a water basin)—the Asparagus roots were planted on the surface of ordinarily roughly-dug well-pulverised soil, the results would be equally satisfactory. It would be advisable on a heavy soil to use a mixture of light, though not rich, soil above and below the roots in order to assist in their establishment. Not much manure would be required for at least two seasons, though it would be advisable to mulch with half-decayed manure at planting time, or before the sun has gained much power. The Asparagus, as all must admit, is really shallow-rooting, or as a writer in a contemporary put it, "the roots strike out horizontally rather than bore down perpendicularly." By planting on a somewhat poor soil and given annual top-dressing of manure the roots will be retained near the surface, and be more vigorous and healthy

accordingly. The time of failure with Mr. Nunns appears to be when the roots have worked down into the cold subsoil, and are there either injured by excessive moisture or by some injurious constituent of the soil. In the former case the crowns would be badly matured, and therefore more susceptible of injury from frost or long-continued dampness, than are those plants with the majority of the roots nearer the surface. What strengthens me in the opinion of this being the right solution of the cause of failure, is the fact of much Asparagus being killed during the last severe winter which followed a wet and cold summer.

My advice, therefore, to Mr. Nunns and others is to adopt the more simple style of preparing and planting I have briefly detailed, and which is much the same as far as the act of planting is concerned as that adopted by the French. Probably they were the first to follow this practice; but it is quite certain that shallow planting has long been successfully practised. Larger the French undoubtedly grow it; but I question, if all accounts are true, if they have more profitable plantations than are those of my friends who have single lines of plants between long rows of Gooseberry bushes. In the first instance two-year-old plants were simply laid on the well-broken-up strip of soil, covered over lightly and mulched, and for years they have thrown up good quantities of saleable produce. The soil is a deep retentive loam, and all that now is done is to liberally mulch with good manure every autumn. What great strain upon the Asparagus plants is there that they require such elaborate and expensively made beds?—W. IGGULDEN.

DECEMBER FLOWERS.

To supply a large private establishment now-a-days during the shooting season with sufficient flowers is no light task, for it seems as if nothing can be done without flowers, and their popularity shows no sign of diminishing. Carpet beds and perennial borders may grow or decline in favour, bright colours and sombre foliage may each have their turn for summer decoration, but he who manages to have a large stock of flowers for all purposes during the dull winter months never need fear being out of fashion. A correspondent at page 504 has mentioned a few good plants which flower during the present month, but he by no means exhausts the list, and indeed he omits some of the best. I shall not attempt to exhaust the list either; for instead of this being the dull time of year which many people describe, I take it to be the very brightest period as regards indoor flowering plants with those who have the convenience to grow them. The plants I shall name are all of easy growth, and with one or two exceptions are generally well known. I will take the exceptions first, the most valuable of which is a semi-double Zonal Pelargonium, which appeared in the catalogues a few years ago, and, like many hundred more, has disappeared again because it had no special merit as an ordinary Pelargonium. Probably it was by chance that I found out its peculiar value, and possibly saved it from oblivion. I might, I daresay, have made a pecuniary gain by the discovery had I exhibited the plant in all its glory during the winter months under a new name; but that would have been scarcely honest, and I have already distributed it freely amongst my friends. Unfortunately it rejoices in a horribly ugly name which I cannot pronounce—Guillon Mangilli, and it bears flowers the colours of which I cannot satisfactorily describe, I must therefore send some to the Editors for description; but I can say that it is exceedingly bright with two or three shades of red, varying somewhat in winter according to the temperature in which it is grown. It flowers all through autumn, winter, and spring as freely as a Tom Thumb does in summer, and delights in a stove temperature, where it opens every pip and never damps or grows leggy. It needs no special cultivation beyond a warm house, from 55° by fire heat to 75° or 80° with sun heat and air, and a position where light is unobstructed. Plants six months old in 6-inch pots are now flowering equally freely with plants which have been flowering continuously for almost two years, and I can assure your readers that they will not be satisfied with such varieties as Wonderful and Vesta for winter flowering when they have once seen Guillon Mangilli as it flowers with me. My greatest want in this direction is the same habit in other colours, especially a white one, but Guillon Mangilli seeds only sparingly, and I am afraid we shall have to wait some time for this; however, I have a few seedlings from it for trial. A good double or semi-double white which would flower perpetually and bear stove treatment would be invaluable. I do not underrate single-flowered Pelargoniums, indeed I prefer them for summer flower beds, but they are of little use for cutting.

Another plant more generally known than the above, but not so much nor so well grown as it deserves to be, is the Celosia or Feathered Cockcomb. Imagine plants 18 inches or 2 feet high

in 7-inch pots clothed with plumes as graceful as *Humea elegans*, and of a bright gold or crimson colour. Seed has to be sown in May or June, and the young plants grown in a frame in a similar way to Balsams, then taken into heat in the autumn and treated about the same as Poinsettias, which will bring the plumes out to perfection. There has not been sufficient care taken yet in the selection of seed of this plant by the trade, or it would have advanced to a stage much nearer perfection. It is very variable, and I find that even one year's selection has made a great stride.

Yet another useful annual for winter flowering is the *Browallia*. *B. clata grandiflora* is probably as good as any of them. Its colour is bright blue; and although it has a leggy habit when grown naturally, it assumes a very neat and branching habit when treated in the way I recommend—viz., sow seeds in spring, and when sufficiently large to handle place three plants round a 7-inch pot, and let them grow up as tall as they will till about the beginning of September, by which time they will begin to flower and their stems will have become somewhat hard; then cut them down to about 9 inches from the pot, and they will break out abundantly and may be removed from the cold frame or even from outdoors to a minimum temperature of 55°, where they will grow and bloom profusely, producing flowers inferior only in name to the Forget-me-not.

Carnations, of which I have a house 56 feet by 16 full of flowering plants ten months old, are grown in the same way as described by me in this Journal some years ago, are quite indispensable, and are of such easy culture where there is convenience that it is difficult to imagine why they are not more generally grown; but somehow most people have an idea that there are great difficulties in their cultivation, and either do not attempt it at all, or they do so with plants which have been stunted, and as a natural consequence they fail. The flowers when cut will last a week in water, and we sometimes cut more than a hundred in one day during midwinter.

Gesnera refulgens is in full beauty now, its tall spikes of red Foxglove-like flowers mounted above its warm-looking brown velvet foliage makes it a particularly welcome plant for Christmas, when, for some reason which I cannot adequately describe, bright colours seem to be more enjoyable than at any other time. *G. zebrina splendens* with its green and brown leaves, and its reddish orange and yellow flowers, is now past its best, and *G. cinnabarina* with duller-coloured foliage and brighter flowers than either of the preceding, will not flower for another month, and will carry on a succession of *Gesneras* to the end of February.

Zygopetalum Mackayi, which is perhaps the easiest grown of Orchidaceous plants, is just ready to open its sweet-scented beautiful violet and white flowers in great abundance, which will last a long time either cut or on the plant, and *Epiphyllum truncatum* varieties are very gay, as they never fail to be at this time of year.

Among other flowering plants not mentioned by "FLORIST" at page 504 are *Mignonette*—Miles's Spiral is a good winter variety—Roman Hyacinths, which even those who have no love for the ordinary Hyacinth, and I am one, cannot fail to appreciate; Violets, of which Marie Louise is the most generally useful; *Richardia æthiopica*, or Lily of the Nile; *Bougainvillea glabra*, which will almost always admit of a small faggot of flowers and bracts being cut out without being missed; and a scarlet climbing *Tropæolum*.—WM. TAYLOR.

[The *Pelargonium* trusses are splendid. The flowers are semi-double; the prevailing colour of the upper petals is scarlet, brightening towards the base and shading to crimson at the edge; the lower petals are very rich pink, tinged with pale purplish magenta. The trusses with their stalks inserted through holes in a board, and firmly wedged with cotton wool and strong pegs, arrived as fresh as when cut, the board resting on supports 3 inches from the bottom of the box, which the trusses faced. The trusses packed in the ordinary manner on the false bottom, and filling the box, did not arrive in such good condition.—EDS.]

PRUNING YOUNG FRUIT TREES.

I HAVE recently planted some Apricots, Plums, and a Peach, which I purpose training fan shape. They are strong and healthy, and contain from five to nine shoots each. Should the shoots be nailed at their full length or shortened back? and if so, how much and when? They were planted a month ago. Some of the trees, especially the Peach, are almost perfect in form.—B. E. W.

[As this letter pertains to a subject of great and general importance we submitted it to a gardener who has had much experience with fruit trees, and his reply will be useful to others beside our correspondent. It is as follows—

Dwarf-trained wall trees should not be pruned and permanently

secured to the wall now, but the branches should be fixed in their places to prevent injury by the wind dashing them against the wall; but they must be attached loosely, so that the branches easily slide through the shreds as the soil and roots settle, for there is generally some settlement with newly planted trees. Pruning should be done in the spring, the branches being regularly disposed, and so thinly that the leaves of one branch do not overlap those of another. If the spurs and leaves of a fruit tree cover a space of 9 inches the branches of that tree should not be less than 10 inches asunder. That is a safe rule to follow.

In trees to be trained on the fan shape it is of great importance that the lower branches are strong, and when pruned they should be left of greater length than those above them, and their growth should always be encouraged to be in advance of the others. For this purpose the branches should be trained as much above the horizontal line as possible, and their ends at least should always curve and point upwards for the first few years. It must be remembered that the more nearly a branch is trained to the horizontal line the less freely it grows; and the nearer it approaches a vertical position the more luxuriant it becomes. If the lower branches of the young trees are weak we should not hesitate to remove them, and thus secure a strong base, which is the only sure foundation for producing a well-furnished and well-balanced tree that leaves no space at the base of the wall unoccupied. As you have plenty of branches you can well afford to remove those near the ground if they are much weaker than the others. Retaining weak basal branches and training them in the first instance horizontally, or nearly so, is a grave mistake, and the cause of unsightly trees and vacant space on the lower portion of a wall.

In pruning the trees, if the branches are not shortened sufficiently the buds at the base will remain dormant and the tree become bare in the centre. Every branch should be covered with foliage and fruit buds quite down to the stem of the tree. If the lower branches of the trees are 3 feet long a foot may be cut off them, always pruning to a healthy bud. Assuming that the lower pair, then, are each 2 feet in length, the next pair above them should be 3 inches shorter, a little less rather than more; the third pair from the ground being shortened in the same proportion, and the central leader, if there is one, shortened to about a foot. This leader will produce one pair, or perhaps two pairs, of young branches during the summer, besides the terminal growth. If there is not a central branch two shoots may be trained in summer from each of the branches nearest the centre for forming permanent branches, and so on until sufficient are secured for covering the wall. There is no difficulty whatever in furnishing the upper portion of a tree, and special attention should be given to the lower branches, always keeping them in advance of those above them. The base buds start more freely if the branches are not shortened until a decided sap movement is shown in the spring by the swelling of the buds. Indeed I have often found it advantageous to allow the terminal growths to attain a length of half an inch or more before shortening the branches. When the growths are weak, and, as they should be then, closely pruned, the knife may be employed sooner, or immediately the buds commence swelling.]

FLORISTS' FLOWERS.

AURICULAS.—If there be any time when the beginner in Auricula growing requires faith it is now. He has seen one by one the large fleshy leaves falling off and his plants reduced to very small proportions, but he need not be afraid if they are healthy and out of the way of drip and over-much moisture. They will need but little attention now, and require water but very seldom. The mild weather is so far favourable to the increase of green fly that it will be necessary to examine the plants from time to time and brush them away. For the same reason slugs and snails are troublesome, and should be trapped; they oftentimes nibble away at the crown of the plant unperceived. The unusual quantity of autumn blooming does not seem to promise well for a very good bloom next season.

CARNATIONS AND PICOTÉES.—Those in pots will require overhauling now and then to keep the pots clear of weeds and the plants of mildew or aphides. Where spot appears it is best to cut off the leaves on which it is. If green collects on the surface of the pots the soil should be stirred. Frames should be left open on all occasions when frost does not prevail, and care taken that rain does not reach the plants. When in beds they should be looked over occasionally, especially after frost, and if they have become loosened should be gently pressed into the ground.

PANSIES.—Dead leaves should be picked off and the surface of the pots stirred. They will now be showing signs of growing,

and those who grow them in pots will now be preparing the compost in which to repot them next month. There is no doubt that the Fancy varieties are meeting with much favour, and are now equalling in shape the Show varieties.

GLADIOLUSES.—It is only necessary now to look over the corms occasionally and to see that they are not damp. Now is the best time for procuring new varieties or adding to the stock. Mr. Kelway's list contains some tempting novelties, and the French growers have considerably reduced the prices of their roots, so that there is an ample field from whence to choose. If the ground has not been already prepared for next year's beds it should be done so at once. Good trenching is the best way to treat it, but in all soils this is not necessary, and where it is done care must be exercised as to the subsoil; if that is not good it should not be thrown up to the surface.

RANUNCULUSES.—Little is now required except to look over them occasionally to see that there is no damp amongst them; from which they are very liable to sustain injury, and I very nearly lost my collection by its being forgotten during my absence from home.

DAHLIAS.—Here again damp is the enemy to be guarded against, especially as the autumn was so wet for lifting the roots; but if kept in dry sand there is little danger, still they require looking over carefully now and then.—**FLORIST.**

THE EFFECTS OF ELECTRICITY ON VEGETATION.

It has been stated (page 355) that, on immersing a small seedling plant for a few seconds in dilute magenta dye it will become only partially stained; that the root will have imbibed the colour, whilst the stem and leaves will have rejected it, the coloured part forming an abrupt division across the junction of the one with the other at the neck or collar just above the surface of the soil. Now, whether the dye has only penetrated the part retaining the colour, or whether it has permeated the entire structure, but meeting with some bleaching agent in the stem and leaves has been deprived of its colour, these are immaterial points in regard to the present purpose; the object being to show that the contents of the stem and of the roots differ in their chemical composition, and that the change is effected at the collar adjoining the earth's surface. Take a fresh-stained plant, and after rinsing in clear water place it on a piece of glass, and having drained it add a drop of dilute sulphuric acid, when the colour will instantly disappear. In all bleaching agents, either by the dew and moisture upon grass, by the peroxide of hydrogen, the chlorides of lime and soda, or the sulphur acids, &c., oxygen is the acting principle. To demonstrate this oxygenated condition procure a piece of blue litmus test paper (to be had of almost any chemist in 2*d.* or 3*d.* books), and cutting a slice or section from any succulent stem, press the cut surface on to the paper, and the latter will become instantaneously reddened, showing the presence of an acid or oxygenated fluid. There is thus in the plant a two-fold or polar arrangement identical with that of the copper wire as shown on page 355, attracting oxygen at one end and rejecting it at the other, which constitutes the first or initiating stage in the construction of a battery, we may fairly infer that a corresponding office is fulfilled in the plant. It has often of late, from the many different electrical phenomena developed in organic life, been surmised that animals and plants, &c., must have some sort of a battery arrangement; yet, for want of this commencement not having been detected, the precise nature of such natural batteries has hitherto been a sealed book.

A galvanic battery consists essentially of two different metals, or other substances, of which it is indispensable that one should possess a greater affinity for oxygen, and consequently be more readily dissolved than the other. For this reason and for its cheapness it is that zinc is generally used, and from which, by its solution in the acid, the electric force is developed, the amount of force resulting being always in proportion to the quantity of metal consumed. By joining a plate of copper at the top of the zinc and bending it down into the acid parallel with the latter, and at a short distance apart, the oxidation and solution which took place at the neck (see fig. 64, page 355) is now transferred to the whole surface of the zinc immersed; the second or copper plate serving only to act as a conductor, collecting the force developed, and putting it in communication at the opposite ends so as to form a connected circuit. Let the upper ends be now divided at their junction with each other, and be connected by the insertion of some moist conducting substance capable of being decomposed, and there will then be precisely the same amount of chemical decomposing force exerted between the upper ends as has been developed in the battery below. The idea has

hitherto been that the force obtained from the zinc has made its way through the acid to the copper, and then travelled upwards and back to the zinc at the other end, forming a constantly circulating passage of the electricity from one metal to the other. In deference to these views the lower half of the metals in the acid are termed poles, whilst the upper ends were named by Faraday "electrodes," from two Greek words—*elektron*, electricity, and *odos*, a way, meaning the way the electricity passes; but more modern views, however, show the matter in a far more consistent light.

It is an unvarying rule that it is not possible to develop one of the two electric states without at the same time producing an equal amount of the other. Hence on the poles in the acid becoming electrically charged by the chemical action taking place, the electrodes, or opposite ends of the metals in the air, are inductively charged at the same instant, each with the respective complementary or opposite condition; so that, instead of its being a transference of force from one part to another, it is, in fact, its equivalent, being brought into existence simultaneously at another locality. The preceding distinction may seem to be a very trivial matter and scarcely worth the trouble of insisting upon, but in reality it is far otherwise; for whilst with the circulation theory it is wholly impossible to explain many of the phenomena of organic life, yet, on the other hand, by the induction principle we are furnished with a clue which at once leads us to their full and clear interpretation.

To return to the seedling plant. It will now be seen that whatever amount of chemical action may be excited by light and sunshine in the seedling leaves, a corresponding amount will be induced at the opposite end—namely, in the root. But there is also another effect now coming into play. The axillary bud, partaking of the influence, is thus forced into action; the central stem elongates, and its crowning tuft of embryo leaves becomes stimulated into growth. Let some small thickish leaf, such as that of *Begonia fuchsoides*, be cut in two, and the lower edge of the upper part be placed for a minute or two in the dilute magenta dye with the point upwards, and then, on being taken and rinsed and examined with a pocket lens, it will be found that the leaf is composed of two different layers—the upper green one retaining its natural colour, but the under surface receiving the stain the same as the roots; different species of leaves showing different arrangement of these opposite conditions. Take a cutting from a scarlet *Geranium* in active growth, and having inserted the cut end in a wineglass of the diluted dye, set it in the sunshine for a few hours, more or less according to the time of year, &c., and it will be found that the stain will have been drawn up through certain parts of the stem and along the centre of the leafstalk into all the ramifications of the ribs and veins occupying the under side of the leaf. Should there happen to be an axillary bud present, a section through this will show that every embryo leaf will also have received its partial colouring in the same way. That this absorption of the stain is due to the expanded portion of the leaf may be proved in the following manner. Let the cutting consist of not less than three fair-sized leaves, and from which cut off the middle one, leaving the stalk still attached with an entire leaf both above and below it. It will now be found, after the stain shall have penetrated the upper leaf, that the decapitated stalk will have been passed by without any of the stain having entered it, and of course any axillary buds would be thus shut out of the circuit in like manner. A good illustration of this fact has recently occurred. A plant of *Abutilon* having two axillary flower buds almost ready to expand had its leaf removed, when the buds, ceasing to grow, shrivelled up and dropped off.

It will hence be understood how it arises that an "eye" or axillary bud is capable of being developed into a separate plant. It contains an entire polar arrangement of leaves and root cells, which, by the chemical action of the primary leaf, are forced by the inductive power into corresponding growth. Now, an entire plant consists of as many separate individuals as it possesses leaves and leaf buds, but which, by being thus massed together, multiply the force for the general purpose of the community. Let a steel magnet be broken in two, and each part will yet have its own north and south pole; or if it be crushed into hundreds, or even thousands, of pieces each fragment, however minute, will still possess its polar arrangement. Let a quantity of these broken portions, or even a handful of small iron nails or iron filings, be dipped into with the end of a magnet and they will attach themselves in strings and clumps by their alternate poles, and may be moulded by the hands into almost any form or shape. In this same manner are plants built up of innumerable minute polar bodies termed "cells," which, by their individual growth and division or multiplication, effect the increase in the general bulk of the structure. Thus, although each leaf and bud constitutes of itself

a single battery, the addition of other batteries being made to the fabric adds an accumulated force to the combination, and thus constitutes the full-grown plant a compound battery. About ten years subsequent to Galvani's discovery of galvanism Volta found out that by combining with the preceding other pairs of metals in a particular manner—namely, in alternate series—an increase of power could be obtained, almost to an unlimited extent; hence the distinction, which is a most important one, between galvanism and voltaic electricity is that one is a single circuit, whilst the other is composed of any number of pairs of elements above one. Galvanism, however, which is the fundamental stage in the latter, is not restricted to the metals, but appertains very generally to almost all bodies in Nature. Thus it has been obtained from the opposition of two different gases—from a combination of blood and muscle; whilst by the use of very delicate instruments a so-called current has been detected between the pith of

Fig. 96.

a tree and the albumen or newly forming growth taking place between the wood and the inner layers of the bark encircling it. We have in this fact a most indisputable proof that an electric agency is at work between the unstainable portions and those which receive the dye; and it is also a well-known circumstance that electro-chemical decompositions invariably take place in a direction at right angles to, or, in other words, transversely through membranes from one side to the other, and that these latter are not the slightest impediment to the passage of electrolysed elements; and hence it is that fluids are passed into and out of plants, not through any apertures or openings, but electrolytically—that is, by “endosmose” and “exosmose,” which in reality is the same thing. It is the general belief that membranes have some sort of power of forming other substances, and hence they

Fig. 97.

are styled “formative” and “præformative,” &c., according to their supposed action. This, however, is altogether unsupported by any known fact, and is only a mere fanciful speculation handed down from the darker ages, and has no foundation whatever to rest on; but, on the contrary, it can be shown practically that they are mere mechanical boundaries of limitation between the two opposing electro-chemical forces by which they are produced, so that they are thus entirely passive, as much so as the shell of an egg. As this is an important fact that hurls a deadly blow at the fundamental basis of existing physiological views of both animal and vegetable life it will require some more confirmatory

evidence than mere assertion, and this the following experiment will be found to supply.

Fig. 96 is a vertical section of a glass vessel half filled with white of egg, and having a flat piece of ivory, G, at the bottom for the two platinum electrodes, E and F, from a small Smee's battery to rest upon. After a time the albumen assumed the forms represented in A and B; but it will be seen by fig. 97 that the divisional line C G between the electrodes in fig. 96 is a vertical section of a membranous wall extending quite across the vessel in fig. 97 (which latter is a surface view of fig. 96), so that we have here a diaphragm electrically formed at the spot where the two opposing forces meet. These, meeting halfway in the direction D D, are deflected at right angles, and so carry with them and extend the albuminous wall transversely in both directions. There are also several other effects illustrated here that are explanatory of various so-called vital actions that will be hereafter referred to.—W. K. BRIDGMAN, Norwich.

BRUSSELS SPROUTS.

THAT there is a great diversity of opinion respecting the best mode of cultivating Brussels Sprouts must, I think, be generally admitted. Excellent results are frequently secured by different modes of procedure; but I think with your correspondent, “G. O. S.,” at page 503, that not only in the point he specially there raises, but also as to the best time of sowing and planting, the experiences of some of your numerous correspondents, large growers in various parts of the country, would be advantageous to the amateur and professional gardener. It little matters how select the number of vegetables required may be, or how small the means at command for culture, this always stands first in its class. My usual practice is to make two distinct sowings, the first with the spring Cabbage; and instead of planting in autumn with the Cabbage as is generally done, the plants are pricked out somewhat thinly under handlights, or in a cold frame, protected from the most severe frosts. Frames are to be preferred, as a larger number may be more readily protected. During winter the land is selected, deeply trenched, and heavily manured, and the plants after receiving the necessary hardening by being left for some time fully exposed, are transferred to their permanent quarters. From these we can gather abundantly at any date after August should they be required, and frequently early sprouts are much relished after a long supply of the summer vegetables. Up to the new year we obtain a heavy crop of well-formed sprouts, during which time the tops are cut and much appreciated at the table, and without any apparent injury to the plants, which are picked over again in early spring and destroyed.

The second sowing is made from the last week in March to the first week in April, as the weather and state of the land permit. The seeds are sown in drills 2 feet apart, and sufficiently deep to allow of the drill being half filled with burnt vegetable refuse, as wood ashes, on which a little red lead is dusted to prevent the ravages of both mice and birds. When the plants are sufficiently large they are thinned to 2 feet apart, and grown in this manner they experience no check as in the ordinary way. From this sowing we have now some fine crops. The stems are a dense mass of hard large sprouts from the soil upwards. From these the tops are not taken, as it not unfrequently happens that the edges of the leaves and sometimes the whole top become injured by the weather, and they are not so remunerative as in the case of the first sowing; but in order to supply a succession of tops through winter the thinned plants are saved, pricked out on a piece of spare land and planted after the second early Peas, a foot apart each way. These are more hardy from being less succulent, and the tops are invaluable as winter greens.—J. W. SILVER, *Farnley Hall Gardens, Otley, Yorks.*

IN reference to “G. O. S.’s” question on page 503, relating to Brussels Sprouts, I think the following may not be out of place in your valuable Journal. The question raised by “G. O. S.” is as follows:—To produce the best of Sprouts ought the crown of the plant to be cut out or not? Having had some experience in growing vegetables, I think I can prove to “G. O. S.” and your readers generally, that it is best to let the crowns grow, as by cutting them out the plants are liable to decay. For instance, if you cut the crowns out and the winter be severe, there is no protection for the sprouts, and the plants are very liable to be killed by the frost. Then, again, with rain, the continuous exposure of the cut surface during wet weather would cause decomposition. But supposing the plants are not killed by the frost or rain, the sprouts might be more plump, though the quantity would be considerably less, as by cutting the crowns out the sap has no outlet except to the sprouts, and as soon as these are removed

the expenses without detracting from the interest of the schedules. After some discussion it was decided to leave any necessary alterations to the Executive Committee. The Rev. A. Cheales then suggested that a small gold instead of the silver-gilt medal should be offered to the affiliated Societies, as he believed it would be much more highly valued. This was seconded by T. B. Haywood, Esq., and it was finally determined to offer a gold medal at cost price to such of the affiliated Societies who desired it. The annexed list of officers and Committee was accepted, and the meeting concluded with votes of thanks to the Chairman, the Honorary Secretaries, and the Treasurer.

LIST OF COMMITTEE AND OFFICERS FOR 1881.—President: The Rev. Canon Hole. Vice-Presidents: George Baker, the Hon. and Rev. J. T. Boscawen, James McIntosh, the Worshipful the Mayor of Sheffield. Committee: H. Appleby, J. H. Arkwright, R. N. G. Baker, Rev. H. B. Biron, *W. Brockbank, Rev. C. H. Bulmer, T. F. Burnaby Atkins, Rev. J. B. M. Camm, B. R. Cant, R. B. Cater, Rev. A. Cheales, Captain Christy, J. Cranston, J. L. Curtis, H. Curtis, J. Cutbush, C. Davies, Rev. J. M. Fuller, Rev. F. H. Gall, T. Graveley, G. P. Hawtrey, *T. B. Haywood, C. F. Hore, R. Hogg, LL.D., T. Jowitt, L. A. Killick, J. Laing, M. T. Masters, M.D., F.R.S., H. K. Mayor, J. Mitchell, G. Paul, W. Paul, J. D. Pawle, *Rev. J. H. Pemberton, Rev. E. N. Pochin, G. Prince, T. F. Rivers, W. Robinson, A. G. Soames, *W. G. Sharp, J. T. Strange, J. Tinsley, C. Turner, H. J. Veitch, and *F. T. Wollaston. Hon. Secretaries: the Rev. H. Honeywood D'Ombraim and Edward Mawley. Hon. Treasurer: W. Scott.

Those names preceded by an asterisk are the newly elected Members of the Committee.

FRUITS FOR COLD DISTRICTS.

AGAIN it is necessary to remind your correspondents that without naming the county wherein happened any particular success referred to their communications are of little value. This especially is necessary in the matter of ripening Grapes without fire heat. Regarding the planting of Apples and Pears, were I again to plant, I would have whole rows of Lord Suffields and Ecklinville Seedlings, and of Pears rows of Marie Louise d'Uccle, and only slight sprinklings of other varieties. That is for market purposes where we want quantity first. I have had no early dessert Apples for three years; and, for the same purpose, here to grow late ones in the face of the American supply is not likely to be profitable. The Apple growers' chance is to defeat the foreigners, and this Lord Suffield accomplishes.

We lately had the history of Lord Suffield, and I think it would be interesting to have that of Ecklinville Seedling. I am the more desirous of the latter, as hereabouts we have an Apple, also hardy, and as like it as possible—that is, as it is grown in the north. My attention was first particularly drawn to it by the very large and handsome unnamed specimens exhibited by Her Majesty at the Carlisle International Exhibition, and it was then I determined to give it a trial to test its hardiness, which has proved so satisfactory. It has many times impressed me that it would be appropriate to give it the name of "Queen's Prize." What says its raiser, or, lacking him, those in authority? A Strawberry, too, I have grown these last two seasons proved to be quite regardless of wet, and, of course, I shall in future plant only that one variety, and a further description of which I will give at some other time.—JOSEPH WITHERSPOON, *Red Rose Vineries, Chester-le-Street, Co. Durham.*

ZONAL PELARGONIUM WEST BRIGHTON GEM.

SPORTS from the old and valuable variety Vesuvius are now numerous, which is the more singular since no other Zonal appears to possess the same property of producing growths differing in such a marked manner from the original. Some of the forms so produced are of great merit, notably the white variety distributed by Mr. Cannell, whose salmon-coloured form is also very free and attractive; and the striped variety, "New Life," is as singular as its name implies. There are also sports of various colours that have originated in different places, but as a rule they have not obtained more than local fame. The variety in question, however, West Brighton Gem, will prove—indeed has proved—of real and general usefulness; it has been frequently exhibited during the past three years, and has proved its worth for both winter-flowering or bedding purposes.

It is a very distinct and fixed sport from Vesuvius, perhaps a shade lighter scarlet than its parent, but it chiefly differs from that variety in having transparent growths and flower stems. The plants are very dwarf and compact, barely exceeding 6 inches in height, producing without topping from eight to twelve shoots on a plant in a 5-inch pot. It is a rapid grower although the shoots are short and slender, and no sooner is a cutting struck than it commences branching, so that the surface of the soil is quickly covered with several shoots which grow in an oblique direction,

thereby very soon forming a dwarf and compact plant, but the flower trusses are upright. As a bedding plant its very floriferous character and dwarf habit will cause it to be extensively used, and that it is a free winter-flowering variety was abundantly evident from the gorgeous mass of bloom I saw on a batch of a thousand plants a few days since at the West Brighton Nursery. But lest it be thought that I am overpraising this variety I may add that its value has been twice acknowledged by the Floral Committee of the Royal Horticultural Society, for last winter a cultural commendation, and in May last a first-class certificate, were awarded for it; while at Brighton, the Crystal Palace, and other places where it has been exhibited high commendations have been granted. The peculiar characteristic of its pale flower stems, similar to those of the old Cerise Unique, renders it a favourite for cutting. The leafstalks are also of a transparent hue, and the centre of the leaves are peculiarly marked with the pale green like the variety just mentioned. It is this singular feature and its dense dwarf habit that render it distinct.

This plant originated at the West Brighton Nursery; and Mr. Miles, the proprietor, after proving its value, obtained a very large stock, with the object, I presume, of offering plants at a price that will bring it at once within the reach of everyone.—MEDALLIST.

FOREIGN SUPPLIES AND HOME PRODUCTION.

WE are entering upon a great change of circumstances in relation to the produce of our country. Foreign competition, although as yet only in its infancy, has reduced the value of our products, and British agriculturists feel its effects in reduced returns. Instead of repining over those inevitable changes it would be more desirable if we energetically endeavoured to face them. There are large tracts of land in this country that might be brought into cultivation, and much that is already in occupation that could be greatly improved so as to yield increased produce. In many cases the rent of the land might be realised with a small additional outlay by planting fruit trees, if only in the hedgerows. Tall standards of Apples, Mussle and Bullace Plums, Damsons, Kentish Cherries, Filberts, and Cob Nuts, all will do well and make a good return. The grass lands may be planted with Pear trees a good distance apart. In wet positions plant Quinces; and in every available spot plant Walnut trees, as they are valuable both for their fruit and wood. In swamps plant Willows, which are as profitable as any crop that can be grown in such positions. Some of the fruits mentioned are sent to this country in large quantities; but English produce, being of better quality, always commands higher prices, which should be sufficient to encourage our growers. The importers deserve praise for their energy, but they set us an example which we neglect to follow.

The following are some of the fruits, vegetables, and plants that are imported in large quantities, all of which could be grown here and of better quality. From Holland we have large quantities of bulbs, Lily of the Valley, Spireas, Walnuts, Horseradish, and Potatoes. Belgium sends Azaleas and Camellias, which could be grown in the west of England almost without protection. Hamburg sends Grapes, which a few ground vineries would produce in better condition. France supplies early Lettuces, small salads, Endive, Radishes, Carrots, Asparagus, and early fruits, and later on Apples, Pears, Tomatoes, Artichokes, &c. Our own little Channel Islands contribute excellent green Figs, Grapes, and Pears; while Italy, Spain, Portugal, and the islands of the Mediterranean stock our markets with fruits which our own climate cannot produce. America sends great quantities of Apples, but they are of inferior quality and will not bear comparison with home-grown fruit. There is consequently every encouragement for the increased cultivation here of many fruits which other nations now supply us with to their own profit.—R. C.

PRUNING LUXURIANT VINES.

I MUST beg to differ from "R. P. B.," especially in the latter part of his notes on "Pruning Luxuriant Roses and Vines" (page 452). I cannot see why hard pruning back young Vines should cause a weakly growth the following season, especially if the Vines have made abundance of roots; and judging from "R. P. B.'s" remarks his Vines must have grown vigorously and strongly, and the main stems must have strengthened considerably, or the main leaves would not have been thrown off—a sufficient indication that abundance of roots were working well. Seldom, if ever, are the main leaves thrown off the Vine when root-action is only moderate; and in proportion to root-action, if confined to a main stem the rod naturally swells. If hard cutting back in all kinds of fruit trees (root-action being good) is productive to luxuriant

growth, why not with the Grape Vine? I shall contend, strong young Vines may be—however insufficiently developed are the lower buds at, say, 1 foot from the border—pruned back to any one of these eyes; if slowly brought on the following season they will produce strong luxuriant growth. Not that I say any advantage will be gained by close pruning back if sufficient eyes will burst into growth to swell or strengthen the bottom of the Vine. Prune an old Vine close back, and it will, in the majority of cases, break into growth from places where neither joint or eyes are perceptible, and if root-action is good the growth will be strong. Why should not strong young Vines produce a luxuriant growth when well cut back, instead of a weak puny one as “R. P. B.” thinks? If fruit is required, large prominent buds are certainly desirable.—SCIENTIA.

GLASS STRUCTURES FOR AMATEURS.—No. 2.

THE annexed engraving, fig. 98, represents the section of a half-span house—a most useful form for a variety of purposes. The

appurtenances at the back are the same as shown in the figure on page 462, and it is not necessary to repeat them here. The following are the references to the section now submitted:—*a*, Vine border; *b*, rubble; *c*, drain; *d*, pillars to carry arches of front wall to allow Vine roots to pass out; *e*, front shelf; *f*, pathway; *g*, back stage; *h*, hot-water pipes, 4 inches; *i*, front lights to open entire length of house with crank and lever apparatus; *j*, ridge lights to open full length of house; *k*, stays for trellis wires for Vines, one stay to each rafter, and wires 9 inches apart; *l*, iron tie-bar, one to each rafter; *m*, suspended shelves over pathway; *n*, border for Camellias or other plants.

It may be useful to refer to the construction of the houses. Economy is often sought by the employment of cheap materials, in which there is no true economy, as the materials to be cheap must be of inferior quality. There is no bargain in bricks badly burned and that will perish with frost, even if they are had for a few shillings less per thousand than properly made and well burned; therefore use good bricks. Mortar made of one part lime and two parts sand will be suitable. In timber avoid cheap

Fig. 98.—HALF-SPAN HOUSE, SECTION AND END ELEVATION.

Scale—a quarter of an inch to a foot.

deals, which on account of the sap they contain are totally unfit for glass structures, where such wood decays in an incredibly short space of time. Sound red deal should be employed, or, better still, pitch pine. In hanging the lights brass connections are more durable than cast iron; the expense of replacing the latter in a few years, presuming them to be employed, will equal the cost of the difference between the two metals. For the ventilating apparatus wrought iron is the only suitable material; cast, from not “giving” when the lights are stiff, snaps. The wires for the trellis should not be galvanised, but the best drawn and annealed, No. 6; the stays and strainers (angle iron) should also be wrought or malleable iron, all painted. For the pathway, where timber is employed, have it creosoted, or it will speedily become a prey to fungus. This more especially applies to the sleepers. In the long run cast-iron sleepers, with a ledge to receive cast-iron grating for pathways, are cheapest.

In forming the rebate in the rafters and sashbars half an inch is deep enough, and a quarter of an inch wide for the reception of the glass, which should be 21-oz. thirds quality, bedded in putty

and scoured with copper tacks. No upper putty should be used, but have the wood dressed off level with the glass. The sharp upper edge of the rebate should be taken off and painted, covering a little of the glass, but not more than the width of the rebate, and the roof will be quite waterproof—more so than when top putty is used. Laps a quarter of an inch wide are ample, being better less than over. Sixteen-ounce glass is cheaper than that recommended, but is more liable to breakage. Drip is a serious matter and often occasions great loss in the keeping of Grapes; it may be almost entirely prevented by having a small groove made in each rafter and sashbar on both sides their entire length a little below the under side of the glass. Stout open lath stages are more durable and in every way better than solid. The colour of paint for stages and also for the house should if in a smoky district be stone, and if in the country the roof may be white. Dark colours are objectionable.

The angle of elevation in the different structures is about 40°, which is sufficiently sharp to allow of the rain passing off quickly. 45° is usually considered most suitable; but the higher the angle

the greater of necessity must be the height of the back wall, as is shown by fig. 99, applied to a lean-to roof to a scale of a quarter of an inch to a foot. It will be seen that when the angle of elevation is 45° the width of the house and the height of the back wall are equal, calculating from the base line a of the quadrant. With an angle of 40° the height of the back wall is diminished by $2\frac{1}{2}$ feet, and *vice versa* for every 5° of arc. In calculating the angle it must be from the base—*i.e.*, top of the front or side lights direct to a point at the same height at the back wall of a lean-to, or the centre of a span. I do not, however, propose to enlarge upon this subject, it will suffice to note that the higher the pitch of the roof the greater the accumulation of heat in the upper angle, on which account it is desirable to keep the slope as low as is consistent with the admission of light. The lower the

Fig. 99.

angle the more equable the temperature at the top and bottom of the space enclosed; but if too low it will tend to drip, and a low pitch considerably lessens the rafter, consequently reducing the extent of surface available for training Vines. For structures where little fire heat is employed 40° is the most suitable angle of elevation. To avoid drip it should not be less than 30° , which will answer well enough for general purposes, and for early forcing 45° is quite sharp enough.—G. ABBEY.

REVIEW OF BOOK.

Anatomical and Physiological Atlas of Botany. By DR. ARNOLD AND CAROLINA DODEL-PORT. Parts 1, 2, and 3. W. & A. K. Johnston, Edinburgh and London, 1880.

THIS work was originally published in Germany, where it was so well received that it has induced the production of an English edition, the accompanying text being translated and edited by D. M'Alpine, F.C.S., Lecturer on Botany at Edinburgh. It is precisely what its title states—namely, an "Atlas of Botany," intended for use in schools or for illustrating lectures. The very clear manner in which the drawings have been prepared and coloured, together with their size, render them admirably adapted for either of those purposes. The object is to convey to the student of botany an accurate knowledge of the chief types of vegetable organisation, the phenomena of fertilisation, nutrition, and growth, the several organs and their functions, in fact everything of structural or physiological importance connected with the life of plants. The three parts we have received fairly indicate the scope of the work. They contain six plates each, size 3 feet by 2 feet, giving representations of portions of plants magnified from fifteen to eight thousand times, the following being the plants selected:—*Salvia Sclarea*, *Volvox globator*, *Mucor Mucedo*, *Drosera rotundifolia*, *Ophrys arachnites*, *Aspidium Filix-mas*, *Puccinia graminis*, *Lilium Martagon*, *Pinus Laricio*, *Schizomycetes*, *Bacterium anthracis*, *Ulothrix zonata*, prothallium of *Aspidium Filix-mas*, *Cycas circinalis*, and *Polysiphonia subulata*. Each part is accom-

panied by a handbook fully explaining the plates, and forming a compendium of botanical instructions, containing all the latest information upon the subjects on which they treat, and excluding all doubtful matter. The following short extracts will suffice to indicate how this is accomplished:—

"*Cosmarium botrytis* belongs to the Desmidiaceæ, a group of unicellular Algae of symmetrical form. The cell appears as if in two halves, owing to a deep constriction in the middle. The protoplasm, coloured by chlorophyll, is usually interrupted in the middle, where a colourless nucleus is often to be seen. In each half-cell the bright green protoplasm is arranged in bands or discs, which bear a definite relation in number and arrangement to the larger globular or oval bodies—the starch-grains—which are single or in pairs, or even more in each half-cell. Besides the green protoplasm and the starch grains there is a colourless fluid in the cell, in which a large number of dark granules frequently occur with an oscillating movement, the so-called 'Brownian' movement. The tolerably firm cell-wall of the Desmids is often covered with warty elevations, longitudinal striations, or wave-like prominences, and thin places or 'pores' also occur. All these markings on the cell-wall, which are characteristic for genera and species, often exhibit a definite arrangement in their distribution and a constancy in their number. Many of the Desmids which live isolated possess the power of slowly changing their place, while those species in which a number of individual cells are united into a filament do not possess that power."

"*Volvox globator*, until quite recently considered by many naturalists as an animal, is the most complicated form belonging to the family of Algae known as Volvocineæ. This family consists of plants made of a number of individual cells united into a rounded colony or cœnobium. Each individual cell is furnished with two vibratile cilia, which, acting in concert, give the whole a slow, stately, rolling motion in the water. Reproduction is of two kinds—non-sexual, in which individual cells of the colony repeatedly divide while undergoing rapid enlargement, and each portion gives rise to a young colony; or sexual, by the blending of spermatozooids and oospheres to form an oospore."

"The common Brown Mould (*Mucor Mucedo*) is one of the commonest of Moulds, and is found growing on the most various substances. There is scarcely any decaying organic substance on which it may not be found. Let a piece of bread, for instance, be put in some damp place where it is protected from evaporation, and it is soon covered with a large crop of this Mould, aerial ascending branches of which develop so luxuriantly as to attain a height of 6 inches. It also occurs on bones kept in damp places and on horse droppings, where it grows very rapidly, since the spores introduced into the body along with the food are not only injured on their way through the digestive canal, but the warmth and moisture favour their growth. The Brown Mould grows in damp situations during the winter, even on papered walls, where it often spreads over the entire wall and rots the paper."

"*Puccinia graminis* is remarkable for a complicated alternation of generations. To complete the cycle of its development there are no fewer than five kinds of reproductive cells, which, however, only develop and give rise to new generations when they are conveyed to quite distinct host plants. Within the last century farmers, whose entire crops were often attacked and partly destroyed by this Rust of Wheat, have recognised some sort of connection between the Barberry (*Berberis vulgaris*) and this rust disease; and we are astonished to find that laws and orders had been issued as early as 1788 and later (1815), prohibiting the planting of the Barberry bush in the neighbourhood of corn fields, long before the fact had an incontestable scientific basis that there really exists the same connection between the Barberry and the Rust as between cause and effect. Modern microscopic investigation has succeeded in proving that connection. De Bary was the first to investigate the subject scientifically, and he has since been followed by a host of others."

"*Bacterium anthracis*.—Of all the Schizomycetes which cause the putrefaction of organic substances, or are the propagators of infectious diseases, none has been better investigated than the living contagium of splenic fever. It was first discovered in the year 1849 by Pollender, and since then has been observed by various physicians and naturalists. It is owing to the joint and hazardous labours of these various investigators, their numerous experiments and attempts at artificial culture in various infusions, that we are at present better informed concerning this Anthrax disease than about any other epidemic of men or animals, and possess a tolerably complete account of the whole history of the development of Anthrax. The researches upon this form may therefore be regarded as directly paving the way for, and as a typical example of, the numerous investigations still likely to be made in connection with contagious disease germs."

It is almost needless to add that the present edition is produced in a style suitable to the high reputation the publishers enjoy. It is stated that it will be completed in forty-two coloured plates with eighteen supplementary sheets. We recommend the work to the attention of all those employed in teaching botany.

THUNBERGIA HARRISII.—I have been so greatly struck with the fine, softly shaded, peach-coloured, trumpet-shaped flowers persistently produced on the admirable winter-flowering climber

in the effective stove of W. D. Hemphill, Esq., Oakville, near this town, that I send a line commending it to the notice of your readers. It contrasted admirably with the yellow maroon annual *Thunbergia alata*, and the brilliant purple crimson of the beautiful *Passiflora kermesina*. *Thunbergia Harrisii* has previously been mentioned with approval in the Journal, and I think it is worthy of the attention of those who desire to have attractive climbers at this season of the year.—W. J. M., *Clonmel*.

AT a general meeting of the ROYAL HORTICULTURAL SOCIETY, held on Tuesday last, the Rev. H. Harpur Crewe in the chair, the following candidates were duly elected Fellows of the Society—viz., Edward Amphlett, Major Carleton, Charles B. Farmer, Mrs. Gibbs, Henry T. Middlehurst, Edward A. Nevill, Hon. Edward Romilly, Lieut.-General Stock, Dr. Stocker, James W. Wallace, and Mrs. Henry W. Williams.

— MR. EDWARD MAWLEY informs us that the NATIONAL ROSE SOCIETY'S SHOW AT SHEFFIELD next year will be held on July 14th, instead of July the 17th, as previously announced, the latter date falling on a Sunday.

— THE extraordinarily MILD AND DRY WEATHER that has prevailed in the south of England during the past fortnight was succeeded by rain on Tuesday last, and the roads, formerly dry and dusty, were converted into mud and slush. For planting and land-working generally December has generally been most favourable, and the month has been an unusually busy one in both nurseries and gardens. The temperature has been exceedingly genial, and the songsters of the woods have been as merry as in spring, while Primroses, Violets, and Pansies are flowering freely in some localities. Those are wise who have taken the greatest possible advantage of the favourable circumstances for advancing garden work generally, as the future weather may be as marked for its inclemency as the past has been for its salubrity. In Scotland we learn that snow has fallen heavily, while the winter is so severe in America that several people have been frozen to death.

— TO encourage the production of NEW FLORISTS' FLOWERS, some of the members of the Floral Committee of the Royal Horticultural Society, at the meeting on Tuesday last, proposed to raise a fund for the purpose of offering a prize of £5 at each meeting for the best new variety exhibited. The suggestion was generally approved, and several gentlemen signified their willingness to subscribe if the idea is adopted, which will entirely depend upon the financial support it receives.

— COMPLAINTS are frequently heard, but for which there is comparatively little occasion, about the difficulty of obtaining a good display of flowers during the last two months of the year. The fact is, by judicious selection, where the requisite means are at command for ordinary plant culture, nearly as satisfactory and effective a show of flowers can be obtained at this season as at any other, though not without a little additional care and attention. This was well shown in the CONSERVATORY AT EWELL CASTLE, the residence of A. W. Gadesden, Esq., where we noticed last week that Mr. Scutt, the experienced gardener, had provided as brilliant an array of flowers as could be expected or desired in December; Primulas, Chrysanthemums, Orchids, especially *Calanthes*, Poinsettias, and the charming *Euphorbia jacquiniæflora*, with many others, gracefully intermingled with Palms and Ferns, producing a display that could scarcely be excelled in the favoured spring months.

— IN the same house was an unusually fine specimen of the handsome *DENDROBIUM CHRYSANTHUM*. It was suspended from the roof in the centre of the house, and upon a growth 3 feet in length it bore about a hundred of its rich golden yellow flowers, that were, however, chiefly confined to the apical half of the growth. Another attractive Orchid, *Odontoglossum Insleayi leopardinum*, was represented by a plant bearing several large flowers, and in vigorous health.

— HOLLY BERRIES FOR CHRISTMAS DECORATION are not so abundant as usual in the neighbourhood of London, and the same complaint reaches us from other districts. The "Hingham Deanery Magazine," which circulates chiefly in a district of Norfolk, has this notice:—

"Oh reader! hast thou ever stood to see
The Holly tree?"

So bare of berries as it stands this year, not one dot of red to relieve the 'green winter of the Holly tree.' Our churches this Christmas will miss, too, the accustomed ivory of the *Laurus-tinus*, our houses the Mistletoe's great pearls. So few of even the hardiest shrubs and trees have blossomed, still fewer fruited. Our faith in next year's productiveness wanes; we grow more credulous—inclined to think that there may be some potency which we cannot fathom in certain numbers, and that so there will be little change for the better until 1881 completes the mystic round of seven unfertile seasons!"

— "I SEE," writes "J. R. S. C.," "that in the December number of the 'Entomologist' Mr. Gregson notes two curious facts concerning the GOOSEBERRY CATERPILLAR (*Abraxis grossulariata*). He collected some thousands of these, and found that about 25 per cent. were ichneumonized; also he observed that the autumn larvæ, that should have hybernated, were in one place he visited full fed in October and ready to turn to pupæ. This, however, must be an exceptional case: in Kent there are swarms of larvæ laid up for the winter in nooks and corners."

— AN African Marigold-like plant that is by no means common is *CLOMENOCOMA MONTANA*, though its bright orange-coloured flower-heads, produced at the present time, render it well worthy of attention. It succeeds under culture in pots, requiring a light turfy loam, and bears the flower-heads on long peduncles, which are thus well adapted for cutting. A cool stove or intermediate house is best suited to it, as a moderate heat is requisite to ensure vigorous growth and free flowering. It is a native of Guatemala, whence it was introduced to England nearly twenty years ago.

— WRITING to us on the mildness of the WEATHER IN LINCOLNSHIRE a correspondent remarks, "We shall soon have spring flowers out if it continues like this. Nay, already the Violets and Primroses are showing their welcome blooms, whilst there is still here and there a stray Rose bloom escaped from the severe weather of two or three weeks ago. We have had some of the most exhilarating December days I ever knew, so bright and clear, and yet mild, and such a freshness in the air; but it is colder now."

— OUR Clonmel correspondent sends us the following note upon the culture and hardiness of *SCHIZOSTYLIS COCCINEA*:—"It is a mistake to suppose the flowers, or advancing flower spike, of this brilliant late autumn and winter-flowering plant will endure many degrees of frost. I distinguish between the leaves and flower spikes. The latter succumbed to 4° of frost in the beginning of November, while the leaves are apparently unaffected though we had 10° of frost last week. Fortunately I had all the stronger-flowering clumps potted in October, and for the past six weeks they have been admired by every visitor—not even scarlet Pelargoniums are more intensely brilliant. It is this

system of growth I wish to commend. I have never seen them so robust or with such fine flowers grown inside. Two methods might be adopted—either to plant them out when they have flowered in a rich herbaceous border, or, if in moderately large pots, plunge them in the border, and towards flowering time supply some liquid manure. The latter system has the advantage that when bringing them inside for flowering the plants experience no check."

— THE peculiar spinose shrub *COLLETIA CRUCIATA* is ordinarily an object of curiosity rather than of admiration, but when flowering it is by no means unattractive. In the temperate house at Kew several small plants in pots are now bearing a profusion of their small white bell-shaped flowers in clusters on the upper portion of the branches, springing from just below the strange triangular spines that impart such a distinctive appearance to the plant.

— MR. HENRY C. OGLE, late gardener to Mrs. Okeden of Turnworth, has been appointed to the charge of the gardens of Mrs. Willis Fleming, Chilworth Manor, Romsey. MR. ALEXANDER SHEARER, who has had a long and successful term as gardener to three Marquises of Tweeddale, has left Ycster, and has been succeeded by Mr. Brown, who has been for a considerable time foreman in the same gardens. Mr. Shearer's skill as a gardener, and the great experience he has had in land improvement, commend him for a further charge, which, we understand, he seeks, and is as able and willing to work as ever.

— IN those gardens where the plant stove is sufficiently lofty to accommodate it, the handsome Palm, *DIPLOTHEMIUM CAUDESCENS* is well worth a place; but it is useless attempting to grow it where there is not room for the magnificent leaves to fully develop. Further, as it is a native of Brazil, a high temperature is required, and an abundant supply of water during growth. The leaves are pinnate, 10 to 12 feet long; the pinnæ narrow, 18 inches to 2 feet in length, closely set, of a glossy green colour on the upper surface and silvery white beneath. The habit of the plant is also very graceful, the leaves rising from a short stem and slightly arching. A young specimen in the Palm stove at Kew is now very noticeable.

— AT the annual dinner of the BRADFORD FLORAL AND HORTICULTURAL SOCIETY it was stated by the Secretary, Mr. West, that the Society was prospering very satisfactorily, as the balance of £32 last year had been increased to £53 this, and they had determined in consequence to increase the value of the prizes and to encourage more competition in the open classes. The Exhibition this season was a great success in every way, and it is desired to render the next even more attractive.

— IT is almost needless to call attention to the beauty and usefulness of *LINUM TRIGYNUM* at this time of year, as the plant is now well known and appreciated in many gardens. But there is still room for extending its culture, and we noticed only last week that in two large establishments where plants for decoration are grown in numbers, amidst a wealth of flowers of many and brilliant shades there was nothing to supply the pleasing yellow hue that would have been so well afforded by a few specimens of this Flax. In another garden, however, it was employed very freely, chiefly small plants in 48-size pots arranged on the shelves of a cool stove; and in combination with the numerous attractive plants that may be had to adorn such a structure at this time of year, it produced as bright an effect as could be desired. Easy culture, quick growth, and a habit of flowering profusely in a young state, are recommendations of no light value.

— AN American contemporary has the following relative to the CHICAGO FRUIT TRADE:—"Practically the fruit season with

us extends from the 1st of April to the latter part of October, although some of the small fruits grown in the far South make their appearance here in February. The total trade of the past year in all fruits amounts to over sixteen million dollars, which is reported as equal to the preceding year, and double what it was some five or six years ago. The statistics gathered and compiled by Mr. Cowles, in addition to giving the quantities of the various kinds of fruit handled here, show whence they come. The fresh fruits consist of Peaches grown in Mississippi, Tennessee, Illinois, Michigan, western New York, Maryland, and Delaware; Pears from Illinois, Michigan, and New York; Plums from Tennessee, Mississippi, Illinois, Michigan, and New York; and Blackberries and other small fruits from the territory extending from Tennessee to Michigan."

— A VERY effective fine-foliaged plant is *ARTOCARPUS CANNONI* when well grown, and is very conspicuous in a group of stove plants arranged with Palms and others of similar elegant habit. The leaves are variable in form, some being deeply cut and others very slightly or almost trilobate; they are large, of a reddish crimson hue, which is particularly rich when seen in bright sunlight, a purple tinge being also observable. It is one of Mr. W. Bull's numerous introductions; is a native of the Society Islands, and was sent out from the Chelsea nursery about five years since.

— MR. ALEXANDER MACKENZIE has by request reported to the Epping Forest Committee of the Corporation on his suggestion that a SCHOOL OF FORESTRY should be established in connection with the Epping Forest, for which he says there are a combination of circumstances in connection with the Forest, all of which, it appears, tend to indicate a hope of success. There are about six thousand acres of land, the improvement and planting of which would form the best possible groundwork for the practical training of the foresters in the future. At the present time few of the woodlands and forests belonging to the English aristocracy are managed with either economy or skill, which would be no longer the case if such a school as is now suggested were in existence in England. There is at present an advertisement by the Indian Office for the selection of five young men, "if as many are found qualified," to be trained in France for the Indian Forest service. Instead of the present system of educating Indian foresters Mr. Mackenzie suggests that candidates be selected from the middle classes, the sons of farmers, foresters, and such practical men; they should have received a fair education and possess a little practical knowledge of soils, trees, and botany; their training at the School of Forestry should include practical forestry, mathematics, engineering, and architecture to a limited extent, surveying, levelling, and land-measuring, book-keeping and geology, also they should have facilities for acquiring at their option Latin, French, and German. The course of study should extend over four years, the first two to be spent at Epping Forest, the third year on the New Forest, and the fourth year at Windsor, where may be seen the full development of the principles commenced by the student at Epping. Mr. Mackenzie urges the Committee to secure the powerful influence of the Corporation in inducing the Government to assist in the establishment of such an institution. The example has been set by America, where a Bill has been introduced to the Senate for the establishment of such a school, entirely at the cost of the country; the want has also been recognised and supplied by most of the States on the Continent.—(*City Press*.)

ROYAL HORTICULTURAL SOCIETY.

DECEMBER 14TH.

THE concluding meeting of the year was well attended, and a very good display of vegetables, fruit, and plants was provided.

FRUIT COMMITTEE.—Henry Webb, Esq., in the chair. Mr. Sage, The Gardens, Ashridge, sent specimens of the late-keeping Grapes

Gros Colman and Alicante very finely grown. The Alicante was very well flavoured, and was put in comparison with Alnwick Seedling grown by Mr. Wildsmith at Heckfield. The latter was thoroughly ripened and somewhat shrivelled, of excellent flavour, and with more flavour than Alicante, and both were superior to Gros Colman. The Gros Colman exhibited by Mr. Sage were beautifully grown and unusually thin-skinned. Mr. Woodbridge of Syon House Gardens exhibited a dish of Lady Downe's, of good flavour but not quite ripe. A letter of thanks was awarded to each of those gentlemen.

Mr. Allan, The Gardens, Gunton Park, sent two bunches of a seedling Grape raised by Mr. Speed of Chatsworth. It is a long tapering bunch like Madresfield Court, and the berries are long oval like that variety. The skin is reddish black, and would probably be quite black if grown in heat. The flavour was not of high merit, and it was considered not superior to others in cultivation. It was thought that the flavour might be improved if grown in heat. Mr. Miles, The Gardens, Wycombe Abbey, exhibited two fruits of the Pine Apple Lord Carington, which had been certificated on a former occasion. Messrs. Veitch & Sons of Chelsea exhibited fruit of Diospyros Kaki var. Schi-Tse grown in the south of France. The fruit is the size of an Orange and of a rich golden colour. It is filled with a sweet, agreeable, gelatinous pulp resembling a preserve. A letter of thanks was awarded. Mr. W. Farren, gardener, How House, Cambridge, sent a seedling Apple called Cantab, which was not of high quality. Messrs. James Dickson & Son, Chester, sent a seedling Apple, which was too far gone to enable the Committee to form an opinion of it. Mr. Jacques, gardener at Davenham Bank, Great Malvern, sent a seedling raised from an American Apple, but it was not possessed of any great merit.

Mr. Gilbert, The Gardens, Burghley, sent fruit of a seedling Cucumber called Montrose Seedling, a very pretty variety, handsomely shaped and not too large. It is a cross between Syon House and Kenyon's Freebearer, and said to be a free bearer and excellent for winter use. The Committee wished to see it again in February or March. Mr. W. Hinds, The Gardens, Canford Manor, Dorset, sent a fine dish of Tomato Trophy, to which a cultural commendation was awarded.

Philip Crowley, Esq., Waddon House, Croydon, exhibited two very large and handsome Citrons grown on a tree against a back wall of an intermediate house. The two fruits weighed 6½ lbs., and the large one 4¾ lbs., and a cultural commendation was awarded to them. Mr. Crowley also exhibited marmalade made from the fruit, which was highly appreciated; also some of the small fruit preserved whole, which formed an excellent preserve.

L. A. Killick, Esq., Mount Pleasant, Langley, Maidstone, exhibited a handsome collection of Apples representing a hundred varieties, for which a silver-gilt medal was recommended.

FLORAL COMMITTEE.—Dr. Denny in the chair. Cyclamens were well shown at this meeting. Messrs. J. Veitch & Sons, Chelsea, contributed a group of Orchids and other plants of considerable beauty and interest; that constituted the great feature of the meeting, as it included several handsome rarities and novelties. The charming little yellow-flowered *Oncidium cheiroporum* was in good form with eight panicles of flowers. *Oncidium Forbesii* had two fine panicles of its large pale chocolate-coloured flowers with an irregular yellow margin. The hybrid *Chysis Chelsoni*, a cross between *C. bracteosa* and *C. aurea*, had a spike of compact cinnamon-tinted flowers, the upper portion of the sepals and petals being of a reddish hue, and the labellum barred inside with crimson. The chaste *Lycaste Skinneri alba* had one pure white flower of great size. *Barkeria Lindleyana* was very attractive with three good spikes of its bright rosy purple flowers. The peculiar *Mormodes Wendlandii* had a long spike of pale yellow flowers, of which the labellum was remarkable for its strange form. *Odontoglossum Andersonianum*, *O. Roezlii*, *O. gloriosum*, *Trichopilia rostrata*, the beautiful hybrid *Cattleya Marstoniana*, and several other Orchids were especially notable. *Acanthophippium Curtisi*, an extremely rare Orchid with rosy flowers, deserves notice, together with *Cypripedium tessellatum*, an attractive hybrid between *C. barbatum* and *C. concolor*, may also be included. Several other plants, for which first-class certificates were awarded, are described in another portion of the report. A very fine bank of Cyclamens was also staged, the plants being in excellent condition, the flowers numerous and large. For the Orchids a vote of thanks was accorded, and a cultural commendation for the Cyclamens.

Mr. H. B. Smith, Ealing Dean Nursery, had a remarkably handsome collection of Cyclamens in most vigorous health, with a great abundance of large flowers. The white flowers were particularly pure and of fine substance. A double white variety was shown, in which the lobes of the corolla were increased in number, seemingly by the addition of another whorl. The very large-flowered *picturatum* and an admirable red variety were exhibited in similarly satisfactory condition. A cultural commendation was freely accorded for this exhibit. Mr. J. Wiggins, gardener to H. Little, Esq., Hillingdon Place, Uxbridge, sent specimens of Sutton's Ruby King and Williams' Coccinea Primulas, with two seedlings named respectively Crimson Gem and Purple Gem, both very striking in colour and with flowers of good size. In habit they resembled Ruby King. A specimen of *Oxalis Ortgiesii* was exhibited by Mr. C. Green, gardener to Sir G. Macleay, Pendell Court, Bletchingley. It is a peculiar species with dull green trifoliate leaves, each leaflet being deeply cut at the apex and purple on the under surface. The flowers are pale

yellow, and are borne on a divided spike at the extremity of a long peduncle. A vote of thanks was accorded to Mr. Green for the plant. Mr. H. Cannell, Swanley, had stands of Zonal Pelargonium and *Salvia* blooms in their customary excellent condition. *Salvia Betheli* was especially fine. The Pelargoniums *Beauté de Lyon* and the white variety "I've Got It" were noteworthy. A group of Primulas was also exhibited, including several new varieties of great excellence. Swanley Red was particularly brilliant; another of a deep salmon tint, and several lighter-coloured varieties were distinct and pretty. Robert White, Esq., Old Road, Lee, sent a Primula named Pentland. It was of moderately good habit, and had large crimson flowers. Mr. W. Pratt, gardener to Viscount Hill, Hawkstone, Shrewsbury, was accorded a vote of thanks for some Poinsettia heads and Chrysanthemum blooms, the former being especially good. Mr. E. Hillier, nurseryman, Winchester, exhibited good specimens of his attractive double Primula Annie Hillier. The plants were very dwarf and compact in habit, the flowers being of good form, very full, white suffused with pink, and slightly fringed. The flowers were also very freely produced.

Mr. W. Iggulden, The Gardens, Orsett Hall, Romford, sent specimens of his *Begonia semperflorens grandiflora*, which were in remarkably good condition, healthy, and flowering profusely. Messrs. Smith & Larke, Ashford and Kensington, were accorded a vote of thanks for a collection of Cyclamens in small pots and well flowered, also some very good examples of Poinsettias in 48-sized pots, and varying in height from a foot to 18 inches. The heads were not of unusual size, but the bracts were very highly coloured. A few wreaths of dried flowers were also sent. A vote of thanks was accorded to Mr. W. Allan, gardener to Lord Suffield, Gunton Park, Norwich, for fine growths of *Lapageria rosea* about a yard long, and from fourteen to twenty flowers each. Mr. Allan also sent some Neapolitan Violets of unusual size that attracted much attention. Votes of thanks were also accorded to Sir Trevor Lawrence, Bart., for cut blooms of Orchids, and Mr. Boller for a group of succulent plants. From the Society's Gardens a large number of handsome plants was brought, including Begonias, Primulas, Ericas, Mignonette, Abutilons, Pelargoniums, Poinsettias, and Hellebores. The latter were magnificent, the variety being *Helleborus niger maximus*, which has large white flowers that contrast finely with the deep green leaves. The plants were in baskets, in which they had been placed when lifted about a month ago, and arranged under glass.

First-class certificates were awarded for the following plants:—

Jasminum gracillimum (Veitch).—A remarkably handsome plant of free growth, with long slender branches bearing large terminal and axillary heads of pure white flowers. The individual flowers are an inch in diameter, with seven to nine narrow lobes. The fragrance is very powerful, and to some persons very agreeable. The leaves are rather small, elliptical, and bright green in colour. The plant is altogether a great acquisition, and is quite distinct from *J. pubescens*, under which name it was exhibited on the authority of the Kew officials; but Sir J. D. Hooker, upon subsequent examination, has determined that it may be distinguished from that species by the number of the corolla lobes and the gracefulness of the habit, which character has led to the adoption of the name given above. It is said to be one of the plants introduced by Mr. F. W. Burbidge when travelling in the tropics for the Chelsea firm. This plant is certain to become highly popular.

Croton Hawkeri (Veitch).—A handsome form, with lanceolate leaves 6 to 8 inches long and 1 to 1½ inch broad, clear pale yellow in the centre, with a bright green apex and a narrow border extending half way to the base. The habit is dwarf and compact, and the variety is one of the most distinct in cultivation.

Croton Cronstadti (Veitch).—Another very distinct and pretty Croton, with narrow pendulous spirally twisted leaves, very deep bright yellow near the base, and becoming dark green, with streaks of crimson towards the tip. The pendulous character of the foliage and the bright colours render the plant very attractive.

Odontoglossum anceps (Veitch).—A distinct and handsome Orchid, with a long spike bearing about four flowers on long stout peduncles. The sepals are narrow, of a reddish chocolate colour, the petals being a pale greenish tint, spotted and barred with chocolate.

Odontoglossum blandum (Veitch).—A dwarf and pretty Orchid, with spikes of nine or ten small flowers, cream-coloured, spotted with bright chocolate. The labellum is somewhat shaped like an arrow-head, white and spotted with purple. The sepals and petals are acute and incurved.

Mormodes Wendlandii (Veitch).—A peculiar Orchid, with a spike about 2 or 3 feet long, bearing several large pale yellow flowers near the summit. The structure of the flower is very remarkable, the lip being especially peculiar, and aptly described by the Rev. G. Henslow as resembling a "cocked hat."

Primula sinensis Swanley Red (Cannell).—A useful variety of compact habit, and good truss of large fimbriated intensely rich crimson flowers. The yellow eye is very marked, and serves to relieve the brilliant colour of the limb.

Primula sinensis Purple Gem (Little).—A variety of dwarf habit in the way of Ruby King. The trusses are large, low in the foliage, and of a fine purplish crimson colour.

Primula sinensis Annie Hillier (Hillier).—A double variety resembling some of Mr. Gilbert's strain in general habit. Flowers large,

very full, of good form, slightly fringed; white suffused with pink. The trusses are of good size and very freely produced.

SCIENTIFIC COMMITTEE.—*Galls on Quercus pseudo-coccifera*.—Large galls were exhibited by Mr. McLachlan from Portugal.

Chrysanthemum Sport.—Dr. Masters exhibited a flower of which one half was pale pink, and known as Mrs. Dixon; the other half was yellow, and called Mrs. Rundle. He also exhibited a drawing of a proliferous spermatoce from Dr. Muller of Australia.—[We print this paragraph as we received it; but there is evidently a mistake on the part of someone, for Mrs. Dixon *Chrysanthemum* is yellow and Mrs. George Rundle white.]

Mr. W. G. Smith exhibited specimens of Vine leaves attacked by *Peronospora viticolor*, which appears to be rapidly increasing in Spain and the south of France.

Culture of Coffee at Mysore.—A communication was read from Col. Puckle upon the culture of Coffee at Mysore, in which the author described the different methods of cultivation and processes adopted for preparing the fruit for the market. He asked for scientific opinion as to the relative advantages of plucking Coffee green or ripe, and as to the desirability of removing the first crops, and as to the choice of berries for the cultivation of seed.

LECTURE.—The Rev. George Henslow first called attention to *Mormodes Wendlandi*, exhibited by Messrs. Veitch, the remarkable

structure of the flowers of which genus has been described by Mr. Darwin ("Fertilisation of Orchids," p. 249), and of which the lecturer gave details. Poinsettias, *Euphorbia jacquiniæflora*, and the Strawberry Cape Everlasting furnished good examples of the power of bracts to assume the attractive functions of and often strongly mimic true corollas. This was also the case with *Darwinia tulipifera*, species of *Cornus*, &c., in which it would be difficult, without examination, not to suppose the inflorescences were true flowers. Primulas also illustrated a similar change only in the calyx, which sometimes became petaloid, as in hose-in-hose varieties. This is sometimes mimicked by an extra corolla called a "catacorolla," the calyx remaining normal; or the calyx may retrograde and assume a foliaceous aspect, when such a monstrosity is called "Jack-in-the-Green." The "heterostyled" and "homostyled" conditions of Primulas were alluded to in connection with processes of fertilisation, in which the pollen from the "thrum-eyed" or short-styled form should be conveyed to the stigma of the "pin-eyed" or long-styled form. When homostyled the stamens and pistil were of equal length, and the plants became self-fertilising, a condition apparently not unfrequently obtained in the cultivated forms of *P. sinensis*, and which is normally the case in certain other species.

SPECIAL PRIZES FOR VEGETABLES.

Messrs. James Carter & Co., High Holborn, offered six prizes for collections of vegetables, there being no restriction as to varieties

Fig. 100.—PEAR FERTILITY.

Twelve dishes were stipulated for, to be composed as follows:—Twelve Onions, three sticks of Celery, twelve Carrots, six Leeks, twelve Turnips, fifty Brussels Sprouts, twelve Tomatoes, three Red Beet, three Cauliflowers, twelve kidney Potatoes, twelve Parsnips, and twelve round Potatoes. The prizes were respectively £5, £3, £1 10s., £1, 10s., and 7s. 6d. Mr. J. Miles, gardener to Lord Carington, Wycombe Abbey, Bucks, obtained the chief prize with a handsome collection including clean, even, and well-grown examples of the following varieties:—Carentan Leeks, Stamfordian Tomatoes, very even; Carter's Perfection Beet, Autumn Giant Cauliflowers, Carter's Schoolmaster and Improved Magnum Bonum Potatoes, Carter's Perfection Brussels Sprouts, Carter's Maltese Parsnip, Carter's Naseby Mammoth Onions, Carter's Jersey Lily Turnip, Long Red Surrey Carrot, and Leicester Red Celery. The second prize was awarded to Mr. Phillips, gardener to Capt. Jackson, The Deodars, Meopham, Kent, who staged a very creditable collection. His Musselburgh Leeks, Carter's Perfection Brussels Sprouts, Naseby Mammoth Onion, and Autumn Giant Cauliflower, and Carter's Incomparable Crimson Celery were particularly fine. Mr. W. Iggulden, The Gardens, Orsett Hall, Romford, followed very closely with neat examples of the principal varieties. Mr. Austin, The Gardens, Ashton Court, Bristol, was fourth. Mr. J. Roberts, The Gardens, Gunnersbury Park, Acton, was fifth; and Mr. J. Hains, gardener to Earl of Radnor, Coleshill House, Highworth, Berks, was sixth. There were nine exhibitors, and all

the collections were of good quality. Messrs. Carter exhibited a large number of Potatoes, comprising about sixty-six varieties, and examples of Scotch Champion, Snowflake, and Wormleighton's Seedling, together with examples of Reading, Nuneham Park, Bedfordshire Champion, and Banbury Onions.

PEAR FERTILITY.

THIS is one of Mr. Rivers' seedlings. As its name implies, the tree is very productive, and it is thought the variety will become serviceable as a market Pear. The following figure and description are taken from the "Gardeners' Year-Book" that is now being published:—

"This is a very handsome, a very beautiful, and a very excellent Pear. It is even and regular in shape, obovate, and terminating abruptly towards the eye, near which it has a suddenly contracted waist. Skin entirely covered with a bright cinnamon coat of russet, which has an orange tinge on the side exposed to the sun. Eye open, with short incurved segments, and set even with the surface. Stalk three-quarters of an inch long, stout, and inserted obliquely to the axis of the fruit without depression. Flesh half melting or crackling, very juicy, sweet, and with a

rich and highly perfumed flavour similar to that of Williams' Bon Chrétien much subdued.

"A very excellent Pear, with a rich and refreshing juice, which is sugary, acidulous, and clean on the palate."

CURRENT TOPICS.

SAWDUST FOR PROPAGATING.—I was much pleased in reading Mr. D. Thomson's notes on this subject at page 500. Sawdust is a cheap, plentiful, and easily procured material in town and country, and for these reasons the information respecting it is valuable and acceptable. Here cartloads of it are burned every month, but after this I shall try some of it for propagating. Perhaps some others besides myself may, however, be wondering how the young roots get on when they are shifted out of the sawdust into the loam. I have rooted cuttings in sand and cocoanut fibre refuse, and the roots formed were both numerous and long, but it always took such roots much longer to obtain proper hold of the soil when potted than those in loam, leaf soil, and sand. Perhaps Mr. Thomson would kindly say if that is the case with sawdust, if the dust is shaken quite away from the roots before potting, and the best way to perform the last operation without check?

GRAPES WITHOUT FIRE HEAT.—I think this may now be considered an annual subject for Grape-growers to write about, and it is to be hoped this may cause many to experiment for themselves on the matter. I am of opinion that if growers would use less fire heat in their vineries during June, July, August, and September than they are in the habit of doing, they would be well pleased with the results. These are the months when the majority of Vines are in full growth; but keeping the Grapes afterwards is a different thing, although Mr. S. Castle (page 499) makes this his chief objection to growing Grapes without fire heat. It is astonishing how well all Grapes and Vines succeed during the four months named without any fire heat; but everyone who has had experience in keeping Grapes in November, December, and onwards must know that frost and damp cannot be kept away without heat of some kind. For this reason no good glass house should be erected without the means of heating it, artificial heat only to be employed in cases of necessity, which will certainly not be through the best months of the year.

GARDEN REFUSE.—Mr. Jggulden has named many ways of employing this with advantage, but he has omitted the most important at this season—that is, the best way to dispose of fruit tree and evergreen bush prunings, now so plentiful. If Mr. Jggulden and others would make these into heaps and cover them with old turf parings, weeds, and sweepings, and then light a fire in the centre of the heap, there would be no occasion to wait for a year or more, as the burning at once converts them into better manure for all purposes than would be the case in any other way.

BRUSSELS SPROUTS.—"To produce the best of Sprouts, ought the crown of the plant to be cut out or not!" asks "G. O. S." on page 503. It may be briefly stated that if the most is desired to be made of Sprouts never take the points out. If the crown is cut before the plants are fully grown it stops their growth to a considerable extent, and if the same is done when full-grown it will cause the side sprouts to start earlier into growth and flower in spring than they would otherwise do. I have never seen any advantage follow taking the crown off before all the side sprouts were gathered.

MELONS AND BOTTOM HEAT.—I know it will occur to some of your readers in reading the remarks of Mr. Crump (page 509) that his experience with bottom heat for Melons falls short of theirs. He does not believe the cold-frame treatment suitable for producing good Melons, because he says he has never met with an example worthy of the name grown under such conditions. This is not very encouraging to the thousands who have no other means of growing Melons than in frames. But that good Melons, both in size and flavour, may be grown in such frames I have had many proofs. I know of no one equal to Mr. Pettigrew of Cardiff in Melon culture. His crops are annually very fine, and dozens of his best fruits are grown in frames without top or bottom heat artificially afforded. My practice agrees with this, as I have been awarded prizes at some of the best metropolitan fruit shows so late in the season as the last day in September for Melons cut out of a two-light frame where they had no artificial heat for two months previously.

TRAPPING BULLFINCHES.—The destructiveness of these birds is admitted, and Mr. Hiam has proposed an alternative remedy to the gun. Bullfinches are no doubt as much valued in towns as they are dreaded in fruit gardens, and the suggestion referred to

"to turn them into cash" is worthy of attention both on the score of "economy and humanity."—A KITCHEN GARDENER.

KITCHEN GARDEN.

WHERE Peas have not been sown outside preparation should now be made for sowing under glass either in cold pits, a late Peach house, or orchard house. The old-fashioned horseshoe draining tiles 3 inches in diameter, or wooden troughs 3 or 4 inches in diameter and depth, may be employed, but where turves can be obtained those cut about 3 inches thick and divided into strips 4 inches wide are best adapted for the purpose. The strips of turf should have a groove cut down the centre half their width and depth on the root side, the seed being sown and covered with fine soil. After the young plants have made some growth they must have light airy positions and be treated so as to insure sturdy growth, and when 4 to 6 inches high they should be planted in drills outdoors in a warm situation. If intended to be planted at the foot of south walls such varieties as Little Gem, Blue Peter, Early Premium Gem, and Unique should be chosen, whilst for the border such as William I., First and Best, and Harbinger, the last-named being a week in advance of the others in commencing bearing. A sowing of Broad Beans for early crop may now be made in turves; the variety Beck's Gem is a good one, and may be planted at the base of walls for a very early crop. If required for exhibition Seville Longpod or Carter's Leviathan may be treated similarly, but will not be suitable for transferring to a position near walls from its greater height.

If the weather be open make a sowing of Peas outside to supplement those sown in November, affording a sheltered position and light rich soil. The dwarf varieties already alluded to are suitable for sowing at the base of walls, and with care will yield very acceptable dishes of Peas some days in advance of those which are more exposed. Early Peas must be carefully protected from birds. Dust the plants while damp with lime or soot, and place sticks to them; small twigs of Spruce, or the leafy twigs of young Beech and Hornbeam, are suitable. A sowing of Broad Beans should also be made outside.

Keep the ground about crops of Cabbages, Lettuces, Onions, and Spinach free from weeds, stirring it occasionally, and rendering plants firm that have been disturbed by frost, removing all decayed leaves, and filling any blanks with plants from the reserve beds. Spinach should be gathered carefully, picking the full-sized leaves only, and allowing the plants plenty of room. Lettuces and other crops subject to the attacks of slugs must be dusted occasionally with quicklime.

To be prepared for frost it is advisable to have a supply of Turnips, Jerusalem Artichokes, and Horseradish in store, also Seakale for forcing. A complete clearing should be made of fallen leaves, and all available surfaces be turned up; even those beneath fruit trees may be pointed over to destroy surface weeds and to produce a neat appearance. Asparagus beds should receive a dressing about 3 inches thick of thoroughly decomposed manure, which should be covered with a similar thickness of soil from the alleys.

FRUIT HOUSES.

Vines.—When the buds in the early vinery are swelling the rods should be examined, especially young Vines; and if the upper part or terminals are taking the lead they must be brought down to a horizontal position, syringing the canes frequently until the lower buds have started, when the rods should be secured in position. Do not disbud hastily, but allow the breaks to advance until the best show of fruit can be discerned, and then disbud gradually. The extra foliage will encourage root-action. Turn the fermenting materials over frequently and add fresh from the reserve, maintaining the heat at about 80°. The night temperature of the house should not exceed 60°, and in severe weather it may fall to 55°. Ventilate a little every day, the temperature ranging from 60° to 65° artificially when the buds are growing, increasing to 70° or 75° with sun heat. It will be

advantageous to cover outside borders with leaves 1 to 2 feet in depth, make them firm, and cover with shutters to throw off rain and snow. The earliest-started Vines in pots will require disbudding, reserving those growths with the most promising bunches, stopping two joints beyond the bunch, allowing more if there is sufficient space for the exposure of the foliage to the light. The laterals below the bunches may be rubbed off, but those from the same joint as well as those above may be allowed more latitude, or if likely to crowd the principal foliage stop them at the first leaf. The temperature by day should be 65° artificially and 70° to 75° with sun heat, and in mild weather it must not exceed 60° at night, whilst in severe weather a few degrees lower may be permitted. If the pots are surrounded with fermenting materials replenish them as necessary to maintain the heat about the pots steady at 70° to 75°. Damp the house and Vines in the morning and early afternoon, and if the weather necessitates sharp firing moisture must be distributed about the house, but not on the Vines, about 8 P.M. When the flowers are showing 70° to 75° will be required, not falling below 65° at night. Assist the setting by lightly passing a camel's-hair brush over the bunches. Afford water as necessary, alternating with liquid manure. Have succession houses and Vines that are intended to be started early in the coming year thoroughly prepared, and repeatedly water inside borders so as to have them in a moist condition. If the internal borders have not been top-dressed lose no time in doing so, removing the loose surface soil, and apply a dressing of turfy loam with a sprinkling of crushed bones. Push forward the pruning of late summer and autumn Vines as soon as the leaves have fallen, cleanse the house, and give the roots the needful attention in top-dressing. If this work is likely to be delayed by Grapes still hanging cut and bottle them, for nothing is of such importance as affording a long and complete rest, which is often very much interfered with by the plants arranged in vineries, for a well-ventilated house is necessary day and night in all weather, except when frost prevails. Plants requiring more heat should be excluded from vineries.

Figs.—To have ripe Figs at the early part of May the trees should be started at once. Trees in pots are preferable to those which are permanently planted out, as at this early season a slight warmth at the roots is very beneficial, providing it be regular and does not exceed 70° at the commencement, as more than this is calculated to produce growth too rapidly. The pots should be placed on pedestals of brickwork of the requisite height, and the bed must then be filled with Oak or Beech leaves and firmly placed together, bringing them up around the pots, taking care that the heat about the pots is not allowed to exceed 70° or 75° at the base. If the plants are small the brick pedestals may be dispensed with, but be careful not to plunge the pots deeply in the bed if the temperature exceeds 70°. If the soil in the pots has become dry immerse them in water until it is well moistened. Commence forcing with a night temperature of 50° and 55° in the daytime, allowing an advance of 5° to 10° more from sun heat. Keep the atmosphere generally moist by damping available surfaces frequently, and syringe the trees twice a day. It is of the utmost importance that the trees have a position where they will be exposed to light. The house in which the trees are planted out and intended to be forced next month for affording ripe Figs early in June, must now be attended to in dressing and securing them to the trellis, ventilating freely until forcing commences, except during frost.

Cucumbers.—The winter plants are showing plenty of fruit, and unless they are extra strong fully two-thirds of it should be removed, as nothing tends so much to weaken them as allowing too free bearing in the early stages. Remove all male blossoms and tendrils, affording a moderate earthing to the roots of previously warmed soil, pressing it down rather firmly. Be moderate in the supplies of water to the roots for the present, a fair supply twice a week will be sufficient. Plants growing in tubs or boxes will require it more frequently. Thin out the growth as necessary to admit light, and encourage fresh growth in the autumn. Plant so as to maintain a continuous supply, but for the next six weeks be careful in stopping. Keep the glass clean so as to admit all the light possible.

PLANT HOUSES.

Stove.—Heat for the roots of plants is not so much advocated now as it was, yet it still has its advocates, for many plants, though not

absolutely needing bottom heat, are benefited by it at some stage of their growth, as in the case of *Eucharis amazonica* and others that have been repotted, and it is particularly valuable for plants that produce few roots or lose them at the most critical stage of their growth—namely, when advanced for flowering, as is often the case with *Poinsettias* and *Euphorbias*. To accelerate the flowering of plants at particular times, or to induce growth in order to secure a tendency to earlier flowering, bottom heat is indispensable. No other means exist of producing so genial a condition of the atmosphere as that of a good bed of fermenting materials, as tan or Oak leaves; a bed 4 feet in depth of those will maintain a good heat for a long time, and materially assist the heating power, especially on cold nights. Where hot-water pipes exist to furnish bottom heat cocoa-nut fibre refuse is generally employed as the plunging medium, and is better than sawdust from not being so liable to foster fungus. The heat from passing through this moisture-laden material tends to maintain a genial atmosphere, and, though not equalling a bed of fermenting materials in that respect, is more enduring and cleanly. To render assistance in this way no time should be lost in preparing the material, giving the house a thorough cleaning, well washing the woodwork and glass. Where means do not exist of affording bottom heat, sufficient piping should be available for maintaining the requisite temperature without constantly having to heat them highly, as nothing induces such an unsatisfactory condition in plants. No economy is so false as little piping, which necessitates keeping the water in the pipes near boiling point when the weather is at all severe.

Light is at this time of year of great importance to plants, and everything should be done to favour its admittance. Roof climbers are usually left until the early part of the year before thinning and regulating the growths, but if it was not attended to in autumn all superfluous growths should now be removed. Some are, however, now in great beauty, such as *Ipomæa Horsfalliæ*, *Bougainvillea glabra*, *Manettia bicolor*, *M. micans*, several *Passifloras*, particularly *P. Madonna*, *P. calycina*, and *P. kermesina*; those with others of an evergreen character should not be disturbed in such manner as will interfere with their flowering. Deciduous climbers will require to be dry at the root, but not so much so as to cause the wood to shrivel; and although the evergreen species are the better for being kept rather dry, it must not be entirely withheld, as that would cause the young shoots and leaves to flag to the serious injury of the plant. Many stove plants flowering at this season do best in an intermediate temperature, lasting much longer and bearing removal for decorative purposes better than those grown in a higher temperature. *Serico-graphis*, *Eranthemums*, *Centropogons*, *Thyracanthus*, *Euphorbia jacquiniæflora*, *Begonias*, *Gesneras exoniensis*, *zebrina* and *splendens*, and the attractive *Epiphyllums*, all do well in a temperature of 55° to 60°, and to have them in the brightest colour the plants must be so placed as to have their heads near to the glass. For forwarding *Richardias* and continuing *Bouvardias* in flower similar conditions as to heat and light are absolutely necessary.

FLOWER GARDEN.

When the leaves have all fallen a thorough cleaning should at once be commenced. The lawn must be kept free from wormcasts by sweeping and rolling, also similarly attending to the walks. Thin out and transplant trees and shrubs where too thick, and the dressing of the borders should be proceeded with as the weather and opportunity offers. Bed and borders edged with Box must have any gaps filled up, and where the edgings have become too large they may now be taken up and relaid. Box does not succeed in all soils, often having a rusty brown colour, which usually arises, except in very sandy soils, from a deficiency of calcareous matter; hence in relaying the colour may be improved by working in a good quantity of fine chalk. Where Box does well it is unsurpassed as an edging plant.

There is always great risk in digging borders of herbaceous plants at this season, unless the position of all plants and bulbs are clearly indicated by stout labels; and although a peg in the case of bulbs and such plants is considered sufficient, yet much is added to the interest of a garden by having them properly named. The borders should now have a good mulching of half-decayed manure, so as to enrich the soil and form a suitable protection against the severity of

the weather. Christmas Roses are greatly appreciated and in request for cutting, and the flowers are much finer and purer in colour when covered with a handglass, which where forthcoming should be placed over the plants at once. Plants of doubtful hardiness, such as Bambusas, Pampas Grass, New Zealand Flax, Chamærops Fortunei, and others of similar character, must be afforded the necessary protection before severe weather; some fresh leaves and bracken with a few Laurel or Spruce branches are generally effective. Plants against walls, such as Ceanothuses and Magnolias, may be protected by tacking a double mat in front of them on the approach of severe weather.

PLANT HOUSES.

Greenhouse.—Admit air freely whenever the temperature exceeds 45°, and employ fire only to maintain the heat at about 40° at night in severe weather, and between that and 45° in the daytime. Where, however, there are no Heaths, but the collection is composed of the freer-growing hardwoods as well as softwooded plants, the temperature may be kept at 40° to 45° at night, and 45° to 50° in the day artificially. Keep a strict look-out for aphides and fumigate upon their first appearance. Heaths cannot be kept too cool if frost is excluded, and in mild weather too much air cannot be admitted. Lachenalias should have positions near the glass, and if supplied with weak liquid manure they will grow and flower better. Attend to the training of Tropæolum Jarratti, T. tricolorum, and others of that section, so as to secure the even covering of the trellis, and assign them light airy positions, keeping the soil moist. Mignonette must only have water to keep the plants from flagging, and should occupy positions where they will receive plenty of light and air when the weather is favourable. Vallota purpurea will be advancing in growth and must not lack water. Some keep this plant too dry in winter, causing the destruction of the old foliage, and are disappointed at flowering time. Any plants requiring larger pots may now be shifted, and if increase be desired they may be divided, preserving as many roots to each portion as possible. Do not remove the offsets as is often done; they will not interfere with the larger bulbs, soon attaining to a flowering size, and pots with a number of flower scapes are more effective than those with single plants. The Vallota succeeds well in turfy loam and requires good drainage, as during growth the watering must be copious, affording a light position. Let Cinerarias advanced for flowering be assisted with weak liquid manure, also Cyclamens and Primulas whenever water is required, giving it only when necessary, and then thoroughly, avoiding as much as possible pouring it on the neck or collar of the plants. Keep Show and Fancy Pelargoniums near to the glass, and where free ventilation can be given when the weather is favourable, affording water very sparingly at present.

Such plants as Acacias and other New Holland plants, being of stronger growth than the fibrous-rooted Cape plants, will require more copious supplies of water whenever they become dry. Camellias are moisture-loving plants, and must not be neglected, as if only once allowed to become too dry at the roots it may occasion the falling of the buds. Azaleas also require careful attention in the supply of water.

TRADE CATALOGUES RECEIVED.

Chr. Lorenz, Erfurt, Germany.—*Catalogue of Flower and Vegetable Seeds.*

Richard Dean, Ealing.—*Catalogue of Florists' Flowers and Herbaceous Plants.*

William Etherington, The Gardens, Manor House, Swanscombe, Kent.—*Descriptive List of Chrysanthemums.*

Address (R. S. C.).—If you write to Messrs. Richard Smith & Co., Worcester, you will probably obtain the information you require.

Strawberry Culture (Civis Britannicus, Bruges).—There are two small manuals on the cultivation of this fruit that may be of service to you; one may be had, price 1s. 6d., from Mr. Hinds, The Gardens, Canford Manor, Wimborne,

Dorset; the other from Mr. Lovel, Weaverthorpe, York, price 1s. Both manuals contain practical and useful information.

Labels for Wall Trees (V. C. B.).—As we have frequently stated, we do not recommend tradesmen or nurserymen; it would be most invidious and unfair for us to do so, as you would feel if you were a vendor instead of a purchaser, and we recommended the articles of someone else instead of your own. You will find all the information you require by consulting the advertising columns of the current and a few past numbers of this Journal.

Asparagus Culture (A Young Gardener).—Both your advisers may be right. In some gardens much preparation of the soil is needed to induce the plants to grow satisfactorily, while in others they will grow well in the ordinary soil without any elaborate preparation. In one of the finest gardens in the midland counties, managed by a gardener of great ability, it is only with the greatest difficulty that Asparagus can be grown; on the other hand we know acres of good Asparagus without the land having been even trenched before it was planted. Read carefully the notes published in the present number, and follow the mode of culture detailed that appears the most applicable to your soil and situation.

Carnations for Christmas (Mrs. Mason).—You are expecting rather too much when you ask "how to treat cuttings of some beautiful Carnations to have flowers at Christmas," at least if you mean the festive season now pending. If you have a moderately heated propagating case, or a warm house, you may insert the cuttings in sandy soil, water them, and cover with a bellglass. If this is wiped out daily and careful attention is given the cuttings may strike, although this is not the best season for striking them, and with proper culture and suitable varieties the plants may be had in flower at Christmas, 1881. We shall shortly publish notes on the cultivation of these flowers and enumerate some good varieties.

Water Melons (A Gardener).—They require practically the same treatment as ordinary Melons, and may be grown in houses or frames. We have grown them successfully by having strong plants ready for planting in May, by which time the frames that had been employed for forcing Potatoes were at liberty. The soil was removed and a few barrowfuls of fermenting materials mixed with the old bed, the soil replaced, and when gently warmed the Melons were planted. They were then watered, pruned, and ventilated as for ordinary Melons, and in due time fine fruits ripened; but they were not by any means equal in flavour to the best named varieties of Melons grown under precisely the same treatment.

Strawberries, Weight per Acre (W. B.).—In our issue of August 26th of the present volume you will find on page 196 an answer to a question on this subject. The estimate is, however, necessarily approximative, as so much depends on the soil and mode of culture pursued, and also on the seasons, all of which circumstances greatly influence the productiveness of the crops. Suitable distances for planting are 2 feet 6 inches between the rows, and 18 inches between the plants in the rows, or about eleven thousand plants per acre. In Kent Vicomtesse Héricart de Thury, syn. Garibaldi, is more extensively grown than any other variety for market purposes. If you apply to Mr. Lovel of Weaverthorpe, York, he will send you his pamphlet which has reference to growing Strawberries under field culture.

Lapagerias Dying (W. K.).—You appear to have treated the plants correctly both as regards soil and careful watering. We are inclined to think that the peat contains something that is injurious to the roots. We have had peat that was quite unsuited for Lapagerias, also for Camellias and other plants. We should try some from a fresh source. The water, too, may be injurious, but if the lime is the deleterious ingredient we should expect that Camellias would similarly fail to flourish. You can have the water analysed by your county analyst, but if you prefer submitting a portion to a London analyst we will send you the address of one if you desire us to do so.

Hyacinths (D. M. E.).—The bulbs that are "raised out of the pots" have not been properly potted. The soil on which they rest has been much too firm; and, instead of the mass of roots entering it freely it has by its resistance caused the displacement complained of. If the roots are not more than an inch or two long, which is probably the case, the bulbs should be at once potted afresh, and if the work is done with great care the Hyacinths will flourish. As much of the soil must be taken from the pots as will enable you to hold each bulb in the left hand in the centre of the pot, the roots hanging so that they do not touch the bottom; then with the right place in the soil carefully, not pressing it about the roots, which are very tender, but giving instead a few smart raps of the pot on a firm bench, still holding the bulb with the hand. When the pots are filled with soil it may be pressed down round the sides, but the bulbs must not be pressed down, nor the roots crushed. Water them immediately through a fine rose, and cover with cocoa-nut fibre refuse for about three weeks, by which time they will be well established. When the bulbs are partially upheaved and not rectified the plants are never satisfactory, as the spikes grow in a slanting direction and are with difficulty staked upright to show them to advantage.

Arrangement of Hot-water Pipes (G. S.).—If the pipes rise directly from the boiler to the level of the house, as they should do, only the slightest possible rise in the flow pipe is requisite through the house; indeed if the vertical portion from the boiler to the house is considerable the water will circulate freely through the pipes if they are placed quite level. Four-inch pipes are preferable to 3-inch because of their greater heating surface, and because, the volume of water being greater, the pipes do not cool so quickly after being heated; 3-inch pipes, however, are preferable for certain small structures where the heat from larger pipes would be excessive. We do not recommend the plan of having very small or 2-inch flow and return pipes for connecting the 4-inch pipes with the boiler, although we know the plan is adopted in many places, and apparently answers well. We are unable to advise you on the other subject you mention; your own ingenuity will be of far more value to you than any information we can convey.

Heating Greenhouse (P.).—Your proposed plan of heating as described in your letter, not as shown in your sketch, will answer. If you have a stage you may have the flow pipe under it if you choose by sinking the boiler, or if you have a bed the pipe may be as you propose. The bed will answer very well; and by placing some plants on inverted flower pots, and not needlessly spilling water, the bed will not be too moist in the winter. The flow pipe should proceed from the top of the boiler, with a vertical rise of a foot or two, then very gradually rise to the opposite end of the house, the air pipe being inserted at the highest point, to return as you propose, and enter the bottom of the boiler. By this arrangement the circulation will be certain, and a flow and return 4-inch pipe, as indicated, will be quite sufficient for your purpose. The propagating pit will be useful. It will be advisable to have a shield of some kind between the flow pipe and the plants—a row of roofing slates fixed on edge would answer, and not occupy much space.

Red Spider on Peach Trees (F. W.).—No good cultivators permit the trees under their charge to get into the state you describe. By keeping the trees healthy—the roots being active, in good soil, and plentifully supplied with water—ventilating judiciously and syringing thoroughly, the trees are kept free from red spider until the fruit commences ripening. If a few insects find their way to the trees when the syringe is discontinued they are easily dislodged by a few thorough washings with the garden engine or syringe after the fruit is gathered. There are two ways of syringing: one is the too common mode of distributing the water gently, as if in fear of disturbing any insects that exist; the other is to carefully direct the water so that it strikes directly on every leaf with such force as to dislodge the insects if there are any. The one mode may be described as playing with the syringe, the other using it. There are numbers of young gardeners and amateurs who either do not know how to employ the syringe effectually, or if they do know are afraid of making their arms ache in the use of it; if this were not so there would not be so much red spider on Peach trees in houses. If Vines are in the same house with Peach trees it is not imperative to cease syringing the latter when the Grapes are colouring. A heavy syringing applied to the Peach trees now and then early in the morning of fine days, when the house can be freely ventilated, will not in the slightest degree interfere with the colouring of the Grapes; but in very hot weather is much more likely to assist them in finishing well.

Grapes for Market (J. M.).—In compliance with your request we forwarded your letter to Mr. W. Taylor, and the following is his reply:—"You have too many varieties of Grapes in your house, and the Vines have been too heavily cropped. Twelve bunches to a rod would give better results than twenty. The best Grape for sale or any other purpose till the end of the year is what is sold as Black Hamburgh or Frankenthal. As you appear to have six of these, they would probably fill your house sufficiently in time if some of the less valued sorts were cut gradually away to make room for the extensions of these, and would give a better return than the seventeen now do. If a late Grape must be grown with them, Alicante or Mrs. Pince would be more likely to succeed than either Gros Colman or Lady Downe's, which require a very long season and the best possible treatment. The late Vines must have the best position, say the south-east corner, and even then you must not be surprised if the fruit does not attain absolute perfection. A border only 2 feet in depth is rather shallow for an inside border, and will require watering very frequently, probably at intervals of eight or ten days during the growing season, and must be mulched from before midsummer till the fruit is cut. If some of the less valued Vines are cut out at once so that the sun has a better chance to assist in warming the house, you might possibly find your flue sufficient; but you should see that the flue is isolated from the surrounding soil and masonry. It ought merely to rest on piers and have nothing touch its sides; and then, although it is below the path, the heat will not be lost if there is an open trelliswork above it. A flue properly built and properly worked is not to be despised for heating a small house, and is generally cheaper than hot-water pipes, although for heating several houses which are near together as well as for a large house hot water is decidedly preferable. A minimum temperature of 55° to 60° during the growing season is all that is required as regards artificial heating to produce the best of Grapes, therefore if the flue is capable of doing that let it remain. Good Grapes such as we see at exhibitions ought to fetch 6s. or 7s. a pound now if sold direct to consumers, or if to a tradesman who has run all risks they will fetch a third less."

Labour for Estate (D. L. G.).—It is utterly impossible for anyone to answer your question without knowing more particulars. Some park and pasture land, when the fences are good, require but little labour; others, where the fences are bad, much labour. Some pleasure grounds, where there are extensive borders to be dug and many shrubs to be moved, pruned, and kept in order, also a great extent of lawn, with some flower beds, need three times the amount of labour that others do where there is comparatively little of such work to be done. Then you afford no idea of the extent of the "beds, borders, and wall trees," and as for the "pumping" no one ought to know so well as yourself how much time it occupies; certainly we have no means of knowing. An active young man would easily manage the houses and plants, and have some spare time for attending to the wall trees and other matters. We have known estates such as the one in question managed by three men, and others not larger affording employment for three times the number—everything depends on their nature and keeping.

Names of Fruits (X. F. Z.).—The specimens you have sent must be of some local variety, which we cannot identify.

Names of Plants (W. G. J.).—1, *Pteris serrulata*; 2, *Pteris cretica albolineata*; 3, *Selaginella Wildenowii*. (*R. S. O.*)—1, Specimen very shrivelled, but it resembles *Cystopteris fragilis*; 2, *Adiantum cultratum*; 3, *Asplenium longissimum*; 4, *Aspidium angulare*; 5, *Hypolepis distans*.

POULTRY, PIGEON, AND BEE CHRONICLE.

CLOVER AS A PREPARATORY CROP FOR WHEAT.

(Continued from page 536.)

IN continuation of this subject we shall show that which the home farmer requires specially to understand—namely, why a crop of Clover is so good a preparatory crop for Wheat. The practical farmer of long experience knows the result, but he is unable to account for it without reference to the scientific chemist, and the researches of men like Dr. Voelcker. There is yet another important point to be considered. Does the organic remains of the Clover plants—their roots, stems, and leaves—after decomposition leave more manure in the land than the Wheat crop can

make use of? If so, we have the means of obtaining a further valuable crop after the Wheat. The questions also arise, If there is a large residue of manurial elements left in the land after the wants and requirements of the Wheat growth has been supplied, what is the nature of it? Is it best suited for the production of another cereal crop, or best suited for a pulse or root crop? If the home farmer read the following quotations from Dr. Voelcker's experiments and observations he will, with a little consideration, be enabled to answer these questions.

We must first refer to the following analysis of Clover roots by Dr. Voelcker. "The roots, having been first shaken out to free them as much as possible from soil, were then washed with cold distilled water, and after having been dried for a while in the sun were weighed, when the square yard produced 1 lb. 10½ ozs. of clean Clover roots in an air-dry state; an acre of land accordingly yielded, in a depth of 6 inches, 3½ tons, in round numbers, of Clover roots. The analysis gives the general composition of the roots—water, 44.675; organic matter, 49.236; mineral matter, 6.089; total, 100.000; containing nitrogen, 1.297; equal to ammonia, 1.575. Assuming the whole field to have produced 3½ tons of Clover roots per acre there will be in round numbers 100 lbs. of nitrogen in the Clover roots from 1 acre, or about twice as much nitrogen as is present in the average produce of an acre of Wheat." This clears up one of the difficulties which we wish the home farmer to remember. The next and highly important experiments "were made upon a Clover soil from part of 11 acre field at Burcott Lodge Farm, Leighton Buzzard, in Bedfordshire, once mown for hay, and left afterwards for seed. The produce of Clover hay was 2½ tons and 3 cwt. of seed per acre.

From the analysis we find, as might be expected, the proportion of nitrogen is largest on the surface soil, where all the decaying leaves dropped during the growth of the Clover for seed are found, and wherein root fibres are most abundant. For the contents of the first 6 inches we have of nitrogen 4725 lbs.; nitrogen in roots, 51½ lbs.; nitrogen in second 6 inches of soil, 3350 lbs. Total amount of nitrogen per acre in 12 inches of soil 8126½, equal to ammonia 9867, or in round numbers 3 tons and 12½ cwt. of nitrogen per acre, equal to 4 tons 8 cwt. of ammonia. This is a much larger amount of nitrogen than occurred in the other soil, and shows plainly that the nitrogen accumulates in the surface soil when Clover is grown for seed, thus explaining why Wheat succeeds better on land where Clover is grown for seed than where it is mown for hay. This, however, is denied by others, who say land cannot become more fertile when a crop is grown upon it for seed which is carried off than when that crop is cut down and the produce consumed on the land. The chemical points brought forward in the course of this inquiry show plainly that mere speculations do not much advance the true theory of certain agricultural practices. It is only by careful investigation that positive proofs are obtained. No manure can be compared in point of efficacy for Wheat to a really good crop of Clover. The farmer who wishes to derive the full benefit from his Clover lay should plough it up for Wheat as soon as possible in the autumn, and leave it in a rough state as long as is admissible, in order that the air may find free access into the land, and the organic remains left in so much abundance be changed into plant food—in other words, in order that the crude nitrogenous organic matter in the Clover roots and decaying leaves may have time to become transformed into ammoniacal compounds, and these in the course of time into nitrates, which I am strongly inclined to think is the form in which nitrogen is assimilated by cereal crops. When the Clover lay is ploughed up early the decay of the Clover is sufficiently advanced by the time the young Wheat plant stands in need of readily available nitrogenous food, and this being uniformly distributed through the whole of the cultivated soil is ready to benefit every single plant."

Our quotations having shown that a much larger amount of nitrogen is left in the soil after the Wheat crop than could be assimilated by it, the next point is, What rotation of cropping is calculated to make the best use of the remaining cereal plant food? In the ordinary four-course it must be remembered that the fallow for roots succeeds the Wheat crop, which would practically go far to neutralise the remaining plant food, except in the case of the Clover lea being foul with Couch Grass, in which case we must not expect that an amount of manure left after the Wheat would be worth our attention. If the Clover lea was clean the Wheat stubble would probably be clean also. It is in this case that we wish to speak of the crop which should succeed the Wheat. Upon all mixed soils or strong loamy land Barley succeeds much better after Wheat than after roots fed off by sheep, and is more likely to produce a good malting sample. We must then adopt a five-course rotation in order to make available the residuary manure. The rotation should be Clover, Wheat, Barley, roots, Lent corn or part Wheat, in which case the Clover may be seeded in the Wheat portion of the fifth lain, the other portion being seeded with Beans and Peas after Lent corn. Now the advantage of this five-course over the common four-course is self-evident, especially upon those farms which derive their profit from the sale of cereal crops. To conclude the subject we shall again quote from Dr. Voelcker's summary of results obtained from his own investigations:—"A good crop of Clover removes from the soil more potash, phosphoric acid, lime, and other mineral matters than any other crop usually grown in this country. There is fully three times as much nitrogen in a crop of Clover as in the average produce of the grain and straw of Wheat per acre. Notwithstanding the large amount of nitrogenous matter and of ash constituents of plants in the produce of an acre Clover is an excellent preparatory crop for Wheat. During the growth of Clover a large amount of nitrogenous matter accumulates in the soil. This accumulation, which is greatest in the surface soil, is due to decaying leaves dropped during the growth of Clover, and to an abundance of roots containing when dry from $1\frac{1}{2}$ to 2 per cent. of nitrogen. The Clover roots are stronger and more numerous, and more leaves fall on the ground when Clover is grown for seed than when it is mown for hay; in consequence more nitrogen is left after Clover seed than after hay, which accounts for Wheat yielding a better crop after Clover seed than after hay. The development of roots being checked when the produce in a green condition is fed off by sheep, in all probability leaves still less nitrogenous matter in the soil than when Clover is allowed to get ripe and is mown for hay, thus, no doubt, accounting for the observation made by practical men that, notwithstanding the return of the produce in the sheep excrements, Wheat is generally stronger and yields better after a Clover crop mown for hay than when the Clover is fed off green by sheep. The nitrogenous matters in the Clover remains on their gradual decay are slowly transformed into nitrates, thus affording a continuous source of food on which cereal crops specially delight to grow. There is strong presumptive evidence that the nitrogen which exists in the air in the shape of ammonia and nitric acid, and descends in these combinations with the rain which falls, satisfies, under ordinary circumstances the requirements of the Clover crop. This crop causes a large accumulation of nitrogenous matters, which are gradually changed in the soil into nitrates; the atmosphere thus furnishes nitrogenous food to the succeeding Wheat indirectly, and, so to say, gratis."

Clover not only produces abundance of nitrogenous food, but delivers this food in a readily available form (as nitrates) more gradually and continuously, and consequently with more certainty of a good result, than such food can be applied to the land in the shape of nitrogenous spring top-dressings.

WORK ON THE HOME FARM.

Horse Labour.—The late open weather has enabled the farmers to complete the sowing of Wheat; a portion of the lain on some farms where the land is constantly cleared of Turnips by sheep will now be sown as fast as the ground is ready. If our plan be adopted—that is, ploughing and seeding simultaneously, the corn will vegetate quickly in all open weather, and the plant become almost as strong as that sown last month. It depends entirely upon the condition of the land whether Wheat should be sown all through January and the first half of February, or whether the land should be held over and sown with Lent corn the first dry time in the spring. Upon good loams or mixed soil in a favourable climate we prefer to sow Wheat until the time named in February, because there is more chance on such land of obtaining a good sample of Wheat than of Barley fit for malting, especially if the land is well farmed, the roots having been fed off by sheep eating cake or corn. The Clover plant is much more likely to succeed in the Wheat than in the Barley, because the Barley is more likely to overstraw and become laid than the Wheat crop. It is difficult to do otherwise with the land left uncompleted as an autumn

fallow than we have advised for several weeks past—that is, to plough the land with a single rafter furrow in order to keep the grass on the surface which the untoward weather has prevented being worked out and carted away in due course. We consider it very unwise to plough it under again with a heavy deep furrow after so much costly labour has been expended in bringing it to the surface. Fallow ploughing will still be the principal work on the farm until completed. A time of comparative leisure for the horses will then have arrived. There will often be carting work to be done relating to repairs, carting timber, bricks, lime, and sand, and in case of frosty weather carting wood from the coppices, such as bavins, hoops, hurdles, and poles. The laying-out of yard dung on to the Clover seeds and carting it for Potatoes and Mangold crops into heap in the field where it will be required for use will need attention, as it will save much time in the busy period of spring. In fact, unless the dung is already in the field at planting time we would prefer applying guano to these crops, and save the time of carting and laying out dung from the homestead; for it often happens the work of planting, using only artificial manure, may be completed in as little time as the carting of dung only, which is a matter of prime importance in a changeable climate like ours.

Hand Labour.—Hedging, ditching, wood cutting in the covers, and planting Thorns will be going on whilst the weather is open. Some work on the farm roadways and about the premises, such as laying out and spreading gravel, may be done; the roadways, however, will never require much gravel if the outsides or water-tables are kept free. Much of the earth may be carted away to the heap for earthing cattle pens, or for making compost in admixture with dung for the pastures. Cattle now will require special attention with regular feeding upon a well-considered plan as to the quantities of roots, cake, meal, and fodder. This remark will apply with double force to sheep which are feeding in the open fields, subject to all the variations of weather. This reminds us of the question put to us to-day by a farmer who has three hundred Down tegs fattening in the open fields. He said, "Can you tell me why my sheep should suffer from the scour, and render it necessary to have some of them killed? I give them as many cut Swedes as they will eat in troughs, and I also give them half a pound each of mixed oil cake and decorticated cotton cake mixed with hay chaff daily." We replied that it is always unhealthy for fattening sheep to eat a full allowance of cut Swedes by itself. Our plan is to give the cake in the meal state strewn over the cut roots, instead of giving the cake broken in the ordinary way and mixed with hay chaff. The detail of feeding makes all the difference, for when Swedes or roots of any kind are cut and given in troughs it is quite impossible to regulate the quantity eaten by each sheep; some of them may eat double the quantity compared with others. It is the same with cake when mixed with chaff. Too much or too little are both injurious to health or proof in the feeding of fattening sheep, for as some considerable time usually occurs between the hours of feeding, neither food counteracts the other like it does when given in admixture. When mixed the roots and meal enter the stomach together, and both act in unison in the maintenance of health and the making of meat. Giving cracked cake with hay chaff is very wasteful, for the animals are sure to rout and seek the cake first in preference to the chaff; nor can the quantity of cake be regulated so well for each animal as when meal is mixed with roots. There is also far less waste if the allowance of roots is moderate, so that the sheep can eat all the bait before leaving the troughs. Again, three hundred sheep are too many to feed in one lot as fattening sheep, for the food cannot be so well regulated as in feeding a flock of half the number, although the shepherd may keep the animals back from the troughs until they are all filled.

SMALL VERSUS LARGE POULTRY YARDS.

A FEW weeks ago you published some valuable notes from your esteemed correspondent "C." on a famous poultry yard in North Wales, which proved the great interest taken in fowls; but I am afraid it would have a tendency to lead the majority of beginners to think that if the successful keeping of fowls depended on such conveniences, they must give up all hopes of ever gaining profit or pleasure from them. To show that fowls may be kept in a very small space in the best of health and condition I will briefly describe the poultry yard of Mr. Evan Clatworthy, Ystalyfera, near Swansea.

During the last half dozen years or more the name of this gentleman has become familiar to all frequenters of poultry shows in South Wales, and many exhibitors at the largest shows in different parts of England have cause to remember the presence of his birds at those shows. At the great Birmingham Show held about twelve months ago one of the Buff Cochins shown from this yard was claimed for twelve guineas, and other birds from the same quarter have been sold at higher prices than that. Upwards of three hundred prizes have been secured during the last three years, and we might suppose that the accommodation for these birds must be of the best possible description; but such is not the case. The whole yard only measures 42 feet long by 27 feet in width. This space is surrounded by low sheds or runs, which are divided into a dozen or more compartments, with wire in front

and a good felt and tarred roof. The top range is divided into upwards of a dozen little coop-like runs, which are most convenient for hatching eggs and chicken-rearing. A narrow path runs round the front of all the runs, and the space in the centre, which measures 27 feet by 12 feet, is laid down in grass.

The number of fowls which are reared and kept in such a small space will astonish many persons. Two hundred have frequently been in the runs at one time! Last year 180 young chickens were hatched; this season they numbered 140. Many are sold for exhibiting and breeding as soon as they are matured enough, and a large stock of birds is always kept on hand. In two of the runs there are a few Partridge Cochins and Black Red Game Bantams of the best exhibition breeds, but Buff Cochins are the most numerous. No expense or labour has been spared to secure the very best birds for stock purposes, and the result is a class of birds second to none in the country. All are characterised by great size, short broad thick bodies, small heads and beautiful clean combs, well tucked up wings, little tail but plenty of saddle feather, abundance of fluff, heavy leg and foot feather, and a rich buff colour. Respecting size it may be interesting to state that Mr. Clatworthy has had cockerels weighing from 9 lbs. to 11 lbs. at six months old, and when full grown they have turned the scales at 14 lbs., while the hens reach 10 lbs. and 11 lbs. Some object to Cochins because they are coarse for eating, but they are certainly not so until they are over one year old, and for rearing to kill while young for the table no other fowl can surpass them.

After seeing so many fowls in such condition on this very small space I naturally asked Mr. Clatworthy what foods he employs. These only consist of the common grains and green food, and as meal Spratt's patent is preferred to all others. Great attention is also paid to keeping the runs clean and free from all accumulations of filth or vermin. After inspecting this yard I am enabled to say that with good management fowls can be profitably kept in a small space in either town or country.—M. M.

[We congratulate Mr. Clatworthy on his great success under the circumstances detailed by "M. M." It cannot be too emphatically impressed upon our readers, that with so small a space the utmost attention possible to cleanliness and feeding is indispensable. In larger yards these points are important, but in a confined space they are all-important.]

CANTERBURY POULTRY SHOW.

THE Kent County Pavilion, in which this Show was held on the Thursday, Friday, and Saturday of last week, is admirably suited for the purpose. All the leading classes of poultry were penned on the upper tier in a splendid light, and the Pigeons occupied the gallery. The appearance the birds presented on the last day of the Show bore testimony to the care with which they had been treated. An ample supply of clean chaff in every pen did much to keep the birds fresh and clean, and they seemed to be liberally supplied with green food. The poultry entries (exclusive of selling classes) numbered rather over three hundred, while the Pigeons were just a few under that figure. The quality of the exhibits was, on the whole, excellent; and as the number of visitors on the later days caused the avenues to be inconveniently crowded at times, we may assume that the Show was, what it deserved to be, a financial success. Messrs. Teebay and W. J. Nichols judged the poultry; Mr. Esquilant the Pigeons.

DORKINGS.—*Coloured Cockerels* (seven), were only a moderate class. First (R. Cheesman) fair in size but rather long in leg, and lighter in colour than we like. Second (J. Collins) better in length of leg, but rather wanting in breast. Third (R. Cheesman) much too upstanding for our taste; h.c., J. Castleman Brown; c., W. Sharp and C. Ratcliffe. *Pullets* (eight) were better as a class than the cockerels. First (Goodwin) good in size, well set down on leg, and full in breast. Second (Cheesman) longer in leg and not so square in frame. Third (Castleman Brown) a neat short-legged bird but small; v.h.c., Sharman; h.c., Collins; c., Wachter. *Silver-Grey Cockerels* (ten).—First and Dorking cup (F. Cheesman) inclined to be long in leg and deficient in breast, nice in colour, and good in feet. Second (Plummer) neat but very yellow in saddle. Third (F. Cheesman) too slim and white in tail; h.c., Wachter. *Pullets* (seven).—First (Wachter) an evenly coloured pullet of good shape and fair size. Second (F. Cheesman) good in body colour, but light in breast and rather slightly made, for which reason we preferred third (Wachter), a squarely-built pullet, but also mossy on breast; h.c., Boissier and Wachter. *Any Other Variety* (six) were a good class, all Whites. First (Woodgate) neat in colour, and fair in size and shape; the cock rather coarse in comb. Second (Foster), the cock very ugly in comb and warm in colour; hen moderate. Third (Wingfield Stratford) nice colour, but the cock very hollow in centre of comb, and the hen's comb crooked; h.c. (Eldridge), the cock good but ugly in comb.

COCHINS.—*Buff Cockerels* (eleven) were a strong class. First (Bloodworth) a rich shade of buff, good in size and shape, but wants middle toe feather to carry off his hocks. Second (Tuke) shapely and good size, but had rather too much tail, and fails a little in colour on wing. Third (Paxon) rather upstanding and has too much tail, colour good.

39 (G. H. Wood) a Lemon, good in shape but not large enough; v.h.c., C. Brown, Jenkins; h.c., Stickings; h.c., Sear, good size and shape but bad comb. *Pullets* (eleven) were a fine average class. First (Paxon) good in shape, colour, and foot feather, but not large. Second (Stickings) much better in size, but not so even in colour. Third (Jenkins) neat foot feather and good shape, but hardly even enough in colour; h.c., G. H. Wood, Bloodworth, Paxon. *Any Other Variety Cockerel and Pullet* (nine).—Cup-and-first (Nettlefold) a very good all-round pair of hocked Partridge, the cockerel very rich in colour, the pullet well marked but Brahma-shaped. Second (G. H. Wood) Whites, the pullet good in size and shape, the cockerel too slim and too large in comb. Third (Sawthorn) Partridge again, the pullet well marked, but the cockerel not bright enough in colour; h.c., Buckland. Blacks in fair condition.

BRAHMAS.—*Dark.*—*Cockerels* (eight).—But for the winners only a moderate class. First (Lingwood) a large massive bird, ticked on breast and white in fluff; a perfect Brahma in shape. One of the Palace team we think, but improved in saddle since then. Second (Breeze) the big one that was at the Dairy Show, unfinished even now. Third (Marsh) very neat in comb, but poor in colour; h.c., Earle. *Pullets* (five) were not a grand lot. First (Lingwood) was, we think, unnoticed at Hull, and deep in moult then; she is now in much better form; her pencilling is good, of the heavy type, failing just a little in breast, and with a brown shade all through. Second (D. Jones) very poor in breast marking, also in saddle, and short of foot feather. Third (Norris) a new one, of the finely pencilled grey sort; we should have put her before second; h.c., Metcalfe. *Light.*—*Cockerels* (thirteen) after the winners were not a very good lot. First and second (G. H. Wood) both fine all-round hocked birds. The first most massive, but rather yellow; the second very neat indeed, and not so warm in shade. Third (Howland) large and shapely, but rather uneven in comb, and too much buff in hackle; h.c., Ive, far too much buff in hackles; h.c., Laurie, Breeze. *Pullets* (fifteen), as a class, showed too much buff. First-and-cup (G. H. Wood) a very shapely hocked pullet, of good size and colour, very neat in head, and splendidly shown; an easy win. Second (Nettlefold) another very nice pullet, not so shapely or clear in colour as the winner, but still a good one. Third (Breeze) very bad in colour, for which reason we should have put h.c. (Morgan) before her; v.h.c. (Bloodworth), either very dirty or bad colour; h.c., Ayliffe; c., Morgan.

SPANISH.—*Cockerels* (fourteen) were a very good class. First (Le Sueur), the second-prize Birmingham bird, we think, not now in such good form. Second (Francis) a moderate-sized face of the old cauliflower type; condition fine. Third (Chatterton) a smart cockerel in good condition, very good quality of face and lobe, comb good but not quite straight at the back; h.c. (H. Brown) a nice quality of face, but not enough of it; h.c., Nash, Butler; c., Francis. *Pullets* (ten).—A rather strong class. First-and-cup (Rogers Bull) the second Palace and first Birmingham winner. Second (Nash) the third Palace winner. Third (Brown) a good quality of face but small; h.c., Shaxby, Woods.

FRENCH (four).—Small in numbers but good in quality. First (Wingfield Stratford) a good pair of Houdans; the pullet very good in crest, and the best of the two; the cockerel seemed wry-tailed. Second (Darley) Crêves, the pullet again being good in crest and muffling. Third (Wingfield Stratford) moderate Houdans, good in crest and comb.

LEGHORNS (thirteen) were a pretty good class, the first alone being Whites, the rest Brown. First (Bradbury Bros.) a neat pair, good in lobe, but the cockerel very heavy in comb. Second (H. Brown) a good Brown pair, the cock, however, heavy in comb and red in lobe. Third (Ayre) Browns also, neat in head and good in lobe; v.h.c. (Verrey) had one of the worst combs we have ever seen; h.c., Gibbs, Adams, and H. Brown.

GAME.—*Black Red.*—*Cockerels* (ten) were a moderate class. First (Theobald) a stylish bird of good reach, but not very bright in colour. Second (G. Dawes) also good in style, and better in colour than the winner. Third (Elliott) a good all-round bird; h.c., Warde and Dawes. *Pullets* (eight) were hardly up to the cockerels in quality. First (Foster) a stylish pullet, close in feather and good in colour. Second, Dawes. Third and h.c., Kingsnorth. *Brown Red.*—*Cockerels* (seven) included some very fine birds. First-and-cup (Mercer) fine in head and good in style and colour, neatly laced on breast. Second (Bond) another good one, fine in head and close in feather. Third (Warde) a close-feathered one also, moderately laced on breast. *Pullets* (six) were also a good class. First-and-cup (Martin) a shapely hard-feathered bird in fine condition. Second and third (Warde) of similar stamp to the winner, and not far behind her; h.c., Mercer; c., Foster. *Any Other Variety.*—*Cockerels* (six).—A good class. First (Colgrove) a good yellow-legged Pile, rather light in hackle. Second (Warde) another of the same colour, also light in hackle. Third (Foster) a large reachy bird of the same sort, rather short in head; h.c., Sutton. *Pullets* (eight) contained nothing very special. First (Warde), second (Colgrove) and third (Theobald) were all yellow-legged Piles.

HAMBURGS.—*Spangled* (six) were only moderate in quality. First (Plattin) Silvers, very good in colour and marking, moderate in lobe and comb. Second (Spendiff) Silvers again, the cock crooked in comb, the pullet rather cloudy on back. Third (Curry) Golden. *Pencilled* were a pretty good lot. First (Walter) a good all-round pair of Golden. Second (Plattin) Silvers of moderate quality. Third (Calcutt) Golden, the cock very neat and clear in lobe; h.c., Hooker and Calcutt.

POLANDS were only two pens; both first (Jarvis) and second (Huish) were Golden-spangled of good quality.

ANY OTHER VARIETY (eight).—First (Winser) a nicely laced pair of Andalusians, the cock rather heavy in comb. Second (Boissier) moderate Minorcas. Third (England) neat Silkies; h.c., Lambert, Andalusians.

BANTAMS.—*Game, Black Red* (thirteen).—First (E. Morgan) a very neat pair, good in colour and in fine condition. Second (Hore) not quite so good in colour. Third (A. Kitchin) bright in colour and in splendid condition, but rather loose in carriage of wing; h.c. (Anns) very good in shape and colour, but rather large; h.c., Ladd. *Brown Red* (six).—First (Vigers) a shapely pair, close in feather. Second Osborne. *Any Other Variety* (four).—First-and-cup (Hore) yellow-legged Piles, good in shape and colour. Second (Vigers) also yellow-legged Piles. Third (Morgan) willow-legged Piles; h.c. (Cobb) neat Duckwings. *Black or White, Clean-legged* (eight).—First-and-cup (Stephens) a singularly neat little pair of Black Rosecombs, good in all points. Second (Miss Bessie Ladd) Black Rosecombs, neat in comb and good in lobe. Third (Astley) the same sort again; h.c., Brett and Nettlefold, both White Rosecombs. *Any Other Distinct Variety* (seven).—First (M. Leno, jun.), a very good pair of Gold-laced, the cock rather heavy in comb. Second (Clarke, jun.), nicely marked Cuckoos. Third (Astley) Japanese; h.c., Buss (Silver-laced) and Hubbard (Japanese); c., Buss (Gold-laced).

DUCKS.—*Rouen* (eighteen).—A fine class. First-and-cup (J. H. Harvey) large in size, and very good in colour and marking. Second, Boulding; and third (Kingsnorth) also good, though some distance behind the winners; v.h.c., W. F. Harvey; h.c., W. F. Harvey, Jarvis, Cheesman, Howard (2), Arter. *Aylesbury* (ten).—First (Weston) a large pair, the Duck especially good. Second, Arter; and third (Hedges), also good pairs; h.c., Barrow, Sear. *Any Other Variety* (seven).—First (Sandum) moderate Pekins. Second (M. Leno, jun.) Mandarins. Third (Woodgate) rather large Black East Indian; h.c., Howard (Pekin), and England (Black East Indian).

TURKEYS (twelve) were a fine average class, but contained nothing of special merit. First-and-cup, Warde; Second, Mayhew; third, Warde; h.c., Phillips; c., Knight.

PIGEONS.

CARRIERS.—*Cocks* (nine).—First and second (Baker) both Blacks; the first best in beak wattle, the second in eye wattle. Third (Fulton) another good Black; v.h.c., Stephens (Dun); h.c., Hale (Black). *Hens* (eleven).—First (Pearce), second (Stephens), third (Baker), all Blacks well placed; h.c., Hale (Dun) and Baker (Black). *Bred in 1880* (eleven).—First-and-cup (Baker) a very promising Black, very even in eye wattle and good in beak wattle. Second (R. Fulton) a Black again, as also was third (Baker); h.c., Byford, Stephens, and Fulton, all Blacks.

POUTERS.—*Cocks* (twelve).—First (Gill) a Red Pied, not very even in rose. Second (Fulton) a Blue Pied failing in bill. Third (Baker) a good Blue Pied, long in limb and narrow in girth; h.c., Butler & Biggs (White), Gill (Silver Dun). *Hens* (twelve).—First (Baker) a Red Pied, rather heavy in body but good in crop. Second (Gill) a Dun Pied again. Third (Baker) a Blue Pied; h.c., Byford (White), Gill (Blue Pied).

BARBS (ten).—First (Baker) a fine Black. Second (Fulton) another of the same colour. Third (Butler & Biggs) a Black, broad and short in head; h.c., Hale (Black).

TUMBLERS (sixteen).—First (Fulton) an Almond, the best in head. Second (Rayner), and third (Baker) were also Almonds; h.c., Curry, (a Red Agate Splash), Pettman (a Long-faced Black), Savage, Baker (both Almonds), S. Palmer (a Long-faced Yellow Agate).

DRAGONS.—*Blue or Silver Cocks* (fourteen).—First (Osmond), second (Howard), and third (Osmond) were all Blues; h.c., Ashbee, Waterman, Winser, all Silvers; Fulton, Dwelly, Howard, all Blues. *Hens* (twelve).—First (Osmond), second (Fulton), third (Sutton); h.c., (Lush, jun.), were again all Blues. *Any Other Colour Cocks* (eleven).—First (Howard) a Blue Chequer. Second (Osmond) a Grizzle. Third (Howard) a White; h.c., Leith (Yellow). *Hens* (eleven).—First (Osmond) a Blue Chequer. Second (Waterman) a Yellow. Third (Howard) a Grizzle; h.c., Howard, Leith, Atkins. *Bred in 1880* (seventeen).—First (Waterman) a Red. Second (Osmond) a Blue Chequer. Third (Dwelly) a Grizzle; h.c., Osmond, Tate, and Ewen; c., Howard, Ashbee, Tate, and Ewen.

JACOBS (eight).—First (Fulton) a Red; second (Avenell) also a Red; third (Fulton) a Black.

OWLS.—*English* (eleven).—First (Weaving), and second (Van Senden) were Blues; third (Brunton) and the two h.c.'s, (Van Senden, Fulton) were all Silvers. *Foreign* (eleven).—First and second (Baker) and third (Theobald) were all White Africans.

TURBIS (nineteen).—First (Fulton) and third (Homes) were Blues; second (Baker) a silver; h.c., Homes (2, Blues), Dungey (White), Fulton (Red).

FANTAILS (twelve) were as usual all Whites, and were a good class. First (Fulton) was splendid in tail. Second, Loversidge; third, Baker; v.h.c., Baker; h.c., Hall, Loversidge (2), Bakewell.

ANTWERPS.—*Short-faced Cocks* (eight).—First and second (Buckland) both Red Chequers. Third (W. Birchell) a Silver Dun. *Hens* numbered seven, all the birds in the list being Red Chequers. First, Weaving; second, Buckland; third, Pettman; h.c., Ashbee. *Homings, Long or Medium-faced*.—*Cocks* (twenty-three) were commented upon by the Judge as a good class throughout. First (Pearce) a Blue Chequer,

as also was second (Ayres), and third (Carvill); v.h.c., (Winser) a Red Chequer; h.c., Leake, Carvill, Ashbee (2), Bowes, Poncia, Hills (all Blue Chequers); c., T. Foat. *Hens* (seventeen).—First (Poncia) and third (Leake) Blue Chequers. Second (Pearce) a Red Chequer; h.c., Ashbee; c., Sutton. *Hatched in 1880* (sixteen).—First and third (Ashbee), as also second (Bowes) were Blue Chequers; h.c., Carvill, Wanser, Crust, and Poncia.

ANY OTHER VARIETY (seventeen).—Cup and second (Baker) with a Turbiteen and a Trumpeter. Third (Thomson) a Priest; h.c., Thomson (an Archangel), Allen (2, an Archangel and a Satinette), Nettlefold (a Magpie).

WATFORD POULTRY SHOW.

THE annual poultry Show in connection with the West Herts Agricultural Society was held at the Agricultural Hall at Watford on Tuesday and Wednesday last. Few places are better adapted for a country show than this hall; and although the competition is confined to persons residing in Herts or within twenty miles of Watford, many pens of good birds were shown. The attendance was numerous, and the Show altogether a success.

The *Dorkings* were pronounced by the Judge to be very good classes. In the Coloured class the first and second prizes went to the Rev. E. Bartrum, the third to the Rev. H. R. Peel. In Whites or Silvers the cup and champion cup of the Show was awarded to Miss Alice Peel for a splendid pen of Silvers; the cock is a fine-bodied bird, excellent in colour. Second, Alterton; third, Snewing.

In the *Cochin* class Mr. G. H. Wood won first and cup with a heavily feathered pen of Partridge; second, Wood; third, Tukey. Mr. Wood also won first for White Cochins with a very good pair.

In the *Brahma* classes the competition was very keen. First, Breeze; second, Leno; third, Breeze. In Light Brahmās, first and cup went to G. H. Wood for a good pen, but the cock was rather light in comb. Second and third, Breeze.

The *Game* were fair classes. First Black-breasted Red. First and third, Moss; second, G. Bentley. The Game cup went to C. Rowley for an unusually good pair of Brown-breasted Red; second and third, Flitt.

The *Hamburgs* were rather poor. First-and-cup (Spangled) G. J. Pointer; second, Miss Lawrence; third, Seward. In the Pencilled class first Pointer; second and third, Viscount Grimston.

In *Game Bantams* the first prize went to the smallest and smartest pen. First, second, and third, J. W. Flitt. In Any other variety first and cup were awarded to Golden Sebrights (Herbert Peel); second to Cuckoos (Wright); third to Japanese (Astley).

In *Crève-Cœurs* and *Houdans* first and cup to H. Jackson; second to A. Longman.

In *Any Other Variety* the entries were very numerous, and many pens of every imaginable kind were commended. The first prize was won by Black Hamburgs (Pointer), second by Plymouth Rocks (Ludgate), third by Polish (Huish).

The *Ducks* were a good class. First, How; second, Thompson; third, Eley. In Any other distinct breed Pekins won first. Cup, Mrs. Peel. Second, East Indian (Lord Ebury). Third, Fancy Ducks, Red-billed Whistlers (M. Leno).

In *Geese* the Judge left out all that were down behind and overfat. His decision seemed to astonish many of the Watford folks, but he undoubtedly was right. First-and-cup, Hill. Second, J. Lloyd.

In *Turkeys*, first-and-cup, Field; second, Leno; third, Longman. Any other variety, first and second, Finch; third, W. Jones Loyd.

Best Barndoor Cock and two Hens.—First, Snewing; second, Leno; third, Viscount Grimston.

The *Pigeons* were a good collection, especially the Tumblers, Magpies, and Fantails. Mr. T. C. Burnell acted as Judge.

LEEDS POULTRY AND PIGEON SHOW.

THIS Show opened on the Tuesday in this week and closes to-night. The poultry entries numbered 540, and the Pigeons 228. Mr. Dixon and Captain Heaton divided the judging of the poultry between them. Mr. J. Hawley judged the Pigeons. The Show was upon the whole a very fine one, and nearly all the classes were well filled.

GAME.—*Any Variety*.—*Cock* (nine).—These Any Variety classes, which we presume were meant to be to a certain extent champion classes, did not fulfil our expectations. First (Brierley) a reachy Brown Red, hard in feather but a trifle heavy in head and flat in shin. Second (Braithwaite) another stylish Brown Red, finer in head but not so powerful-looking as the winner. Third (Clegg) a Brown Red again, well pencilled on breast; b.c., Hodgson (Brown Red). *Cockerels* (thirteen).—First (Brierley) a Black Red, long in reach and good in head, but very faulty in colour on thighs and fluff. Second (Mason) a moderate Black Red. Third (Braithwaite) a Brown Red; h.c., Staveley (Black Red), Hick (yellow-legged Pile). *Pullet* (eighteen).—This was the best of these classes. First (Walton) a shapely willow-legged Pile, fine in head and hard in feather. Second (Brierley) a Brown Red, not the equal of the winner in head. Third (Whitehead) Brown Red again; h.c., Mason (Black Red), Ward (Brown Red); c., Sootheran & Palliser (Brown Red). *Black-breasted Reds*.—*Cock and Hen* (nine).—A moderate class. First (Sales) a reachy pair of birds, but the cock rather heavy in head and brown in fluff. Second (Hemmingway) not so good in style. Third (Staveley) a fine reachy

cock, very brown in fluff. *Cockerel and Pullets* (seventeen) were on the whole a good class. First (Brierley) a very stylish pair of chickens. Second (Mason) good in reach but dull in colour. Third (Sotheran & Palliser) better in colour but not so much style; h.c., E. Shaw, Jowett, Walton, Hick. *Brown-breasted and other Red (except Black)*.—*Cock and Hen* (eight).—Only a medium class. First (Mercer) good in colour but not quite in show form. Second Brierley. Third Mason; h.e., Robinson; c., Cannan. *Cockerel and Pullet* (twenty-two) contained some very good birds. First (Whitehead) a fine reachy pair, hard in feather. Second (Brierley) another good pair, the cockerel will look better doubtless when dubbed. Third (Mason) not so stylish, and the cockerel flat in shin; h.c., Warner, Robinson, Braithwaite, Sturzaker; c., Mercer. *Duckwings*.—*Cock and Hen* (nine).—A moderate class. First (Staveley) a stylish pair, good in colour, the cock perhaps rather short in head. Second (Addy and Carter). Third (Sales) not the equals of the winners in style or reach; h.c., Carless. *Cockerel and Pullet* (eight) contained nothing very remarkable. First (Staveley) hard in feather and good in style. Second (Hick) the cockerel heavy in head. Third (Fell) a moderate pair. *Any Other Variety*.—*Cock and Hen* (four).—First (Mason), second (Walker), and third (Garwood) were all yellow-legged Piles. *Cockerel and Pullet* (seven).—First (Brierley) and second (Mason) yellow-legged Piles, the first a very good pen indeed. Third (Clegg) willow-legged Piles.

DORKINGS.—*Cock and Hen* (eight) a good average class, all the birds being coloured. First (J. White) a good-sized shapely pair. Second (Peacock), the cock rather long in leg and comb, and rather light in colour. Third (Barker) a very shapely hen, of good size, but dark in feet, as also was her mate; v.h.c., Cannan, Carver. *Cockerel and Pullet* (eleven).—Again made up entirely of coloured birds. First (Bell) a good pair, the pullet the best of the two; the cockerel too upstanding for our taste. Second another very similar pair, from the same yard. Third (Baker) a moderate pair, the cock loose in comb; h.c., (King) a fine-sized cockerel, but the pullet out of form; h.e., White.

COCHIN-CHINA.—*Cock and Hen* (twelve) were a strong class. First (T. Pye) a very evenly coloured pair of Lemons, of good size and shape, but the cock wanting more toe feather to carry off his hocks. Second (C. Brown) Buffs, of medium shade, good in colour and squarely made, but the cock loose in wing. Third (Cannan) a very shapely Partridge pair; the cock failing in colour and white in tail, with too much of it; the hen not very good in body marking; h.c., Sowerby (Buffs). *Cockerel and Pullet* (fifteen), not so good as the old birds. First (Cannan) a moderate pair of Partridges. Second (C. Brown) Buffs; the pullet shapely, but not very even in colour. Third (T. Pye) Lemons; the cockerel a good one, but rather loose in comb; h.c., Croft, Mitchell (both Buffs).

BRAHMAS.—*Light Cock and Hen* (nine).—Except the winning pen not a strong class. First (R. Mitchell) was the cup Birmingham cock mated with a very good hen. Second (T. S. Clarke), the cock far too much tail without saddle, and the hen rather warm in colour. Third (Breare) cock very good, but far too warm in colour on saddle; c. (Lucas) the cock rather long in leg and a trifle rough in comb; the hen not over-large, we liked them second best in the class. *Cockerel and Pullet* (nine).—Had no less than six empty pens, and there was nothing really good left. First (T. S. Clarke) a fair pair, the cock rough in comb. Second, Whitehead. Third, Grieve. *Dark*.—*Cock and Hen* (fifteen).—Contained some very fine birds. First and plate for best pen in show (R. Mitchell). The Hull first-prize cock mated, if we mistake not, with the Hull cup hen. Mr. Mitchell apparently means to make it warm for the Brahma men. Second (Brooke), the cock neat in head, good in colour and shape, a little too much tail for his saddle, and hocked; only a moderate hen. Third (Hargreaves) a fair hocked cock mated with the third Birmingham hen; c., Peacock. *Cockerel and Pullet* (twelve) were not a very grand class. First (W. Mitchell) a moderate hocked cockerel, blind of an eye; mated with a pullet nicely pencilled on breast, but failing on other parts. Second (R. Mitchell) the Hull cup cockerel again with his mate of York; on the whole we should have placed them first here. Third (Sowerby) another of the Hull cockerels mated with a fairly marked pullet of the clear-grey type.

SPANISH.—*Cock and Hen* were four only, and not very good. First (Cannan) a large but rather rough-faced pair. Second (Thresh) fair in face but out of sorts. Third (Birch & Boulton) moderate. *Cockerel and Pullet* (four).—First-and-plate for best pen of Spanish, Houdans, Crèves, Polish or Sultans (James Roberts), one of the best faced cockerels we have seen this season, good also in comb and general points; mated with a pullet large in face and lobe, but with comb not over yet. Second (Dalton) a long way behind the winners. Third (W. Roberts) poor.

HOUDANS.—*Cock and Hen* (six) were a pretty good class. First (Cannan) good in colour and the hen good in crest. Second (Turner) not so good in crest. Third (Thomas) a good all-round pen; h.c., W. T. Percival, J. Till. *Cockerel and Pullet* (nine).—A moderate class. First (Thomas) a very good pen of chickens in all points, but not very large. Second (Lee), the cockerel poor in crest and leggy; the pullet a moderate-sized one, of the dark sort. Third (Marx) a pretty cockerel, but the pullet crooked in crest; v.h.c., Millner; h.c., Woolley.

CREVE-CŒUR.—*Cock and Hen* (five).—First (Ward) a fine hen, particularly good in crest and muffling; the cock good in size, but too long in leg. Second (Turner), both birds good in body, but the cock very coarse in head. Third (Cannan) a neat all-round pair, not

so large as the two preceding pens; h.c., Calvert. *Cockerel and Pullet* (nine) with two empty pens, and on the whole a good class. First (Ward), the pullet a good one in all points; the cockerel not so good in crest. Second (Fullerton), the pullet best again; the cockerel rather long in leg. Third (Calvert) of similar type; v.h.c., M. Hall, H. Beldon.

POLANDS.—*Any Variety Cock and Hen* (ten) were a wonderfully good class, and must have been hard to judge. First (Beldon) a well-known pen of Silvers. Second (Rawnsley) Goldens, the hen specially good in crest. Third (A. Smith) Silvers again, the hen very well marked and globular in crest; v.h.c., North and Battye (White Crests), Bowker (Silvers), Cannon (Silvers), Huish (Silvers); h.c., Perry (Silvers), Rawnsley (White Crests), A. Smith. *Cockerel and Pullet* (eleven) were another very even class. First (Rawnsley) a neat pair of White Crests, not quite finished yet. Second (Rawnsley) Silvers moderately marked, but good in crest. Third (Oscroft) better marked Goldens, moderate in crest; h.c., Beldon (Goldens), North and Battye (White Crests), Boothby (Goldens), Bowker (Silvers), Huish (Goldens).

SULTANS.—*Cock and Hen*, numbered six, with two pens empty. First and second (Atkinson) were both good pens, neat in colour, crest, and foot feather. Third (Rawnsley) we should have placed behind the h.c. (Atkinson), as though the cock was very neat, the hen showed a distinct buff shade in her neck hackle.

HAMBURGH.—*Spangled*.—*Cock and Hen* (eleven with four empty pens) were a good class. First (Beldon) Goldens, good in colour and marking, but the cock red in lobe. Second (Bracewell) Goldens again, the cock not very steady in comb. Third (Rawnsley) neat Silvers, the hen very well marked, but a little heavy in comb; v.h.c., Ashton and Booth (Silvers); h.c., Pickles and Rawnsley, both Silvers. *Gold-spangled Cockerels and Pullets* (fifteen) were of very good quality throughout. First (Bracewell) a neat pair, rich in colour and good in comb. Second, another pair from the same yard of similar type. Third (Cannan) not so clear in marking; h.c., Bracewell, Beldon, Moore, Roberts, Rawnsley, Hurst. *Silver-spangled Cockerels and Pullets* (seven).—First (Beldon) good in colour, condition, and marking, and clear in lobe, but the cock not quite even in comb. Second and third (Rawnsley), the former both rather coarse in comb; the hens in both pens very even in marking; h.c., Ashton & Booth, Cannan. *Pencilled Cock and Hen* (eight).—Another fine class. First (Rawnsley) a well-known pen of Goldens, the cock splendid in tail. Second (Beldon) also a very good pair of Goldens, the cock's tail very well marked, the hen not so clear as the winner's. Third (Rawnsley) good Silvers; v.h.c., Jackson (Goldens), Hoyle (Silvers); h.c., East (Goldens). *Golden-pencilled*.—*Cockerels and Pullets* (thirteen) contained some pens of very high merit. First (Driver) a very good pair in all points. Second (Rawnsley) inferior only in the marking on the pullet's breast. Third (Kidson), another very good pair; v.h.c., Webster (2), Simpson. *Silver-pencilled*.—*Cockerel and Pullet* (nine) with two empty pens. First (Cannan), neat in comb, good in lobe, and fairly marked. Second (Rawnsley) also a good all-round pair, the cockerel very good in tail. Third (Pickles) not so good in the marking of the tail of the cockerel or breast of the pullet as the other two; h.c. (Beldon) a very good pair, seeming rather overdone. *Blacks*.—*Cock and Hen* (nine).—First (Bracewell) good in style and brilliant in colour, not quite clear in lobe, and rather heavy in comb. Second (Beldon) a very stylish pair, neat in head, but also rather pink in lobe. Third (Rawnsley), the cock very lustrous in plumage, but perhaps a trifle large; h.c., Mallinson, Lancashire. *Cockerel and Pullet* (sixteen).—A very good class indeed. First (Pemberton) good in style and colour, neat in head, and clear in lobe. Second (Beldon) another very similar pair, not quite so brilliant as the winners. Third (Lancashire) a very good pair, the cockerel a little rough in comb; v.h.c., Mallinson, Rawnsley, Wood & Hirst, Bentley, Hobson; h.c., Simpson.

ANY OTHER VARIETY.—*Cock and Hen* (eight).—First (Calvert) a fine upstanding pair of Malays. Second (Riley) a really good pair of La Flèche. Third (Twose) moderate Andalusians; v.h.c., G. Burnell (Malays); h.c., Brooke (Malays), B. Smith (White Leghorns), Bailey (Malays). *Cockerel and Pullet* (seventeen).—First (Rawnsley) Sultan chickens; we think properly entered, as the Sultan class was limited to birds over a year. Second (Brooke) another good pair of Malays. Equal second (Calvert) good La Flèche; v.h.c., Hurst (Brown Leghorns); c., Clarke (Minorcas), B. Smith (Brown Leghorns).

BANTAMS.—*Game Cock, any variety* (ten).—Beyond the winners only a moderate class. First (Walton) a stylish Black Red, perhaps a trifle short in head. Second (Craven) a good willow-legged Pile. Third (J. Smith) a very neat Duckwing; c., Walshaw (willow-legged Pile). *Reds*.—*Cock and Hen* (eight) were all Black Reds. First (Jennings) very smart, shapely, and brilliant in colour. Second (Walton) not so good in carriage of wing as the winners. Third (Calladine) a smart cockerel, failing in colour on breast; c., Hore. *Cockerel and Pullet* (eight).—First and plate for best pen of Bantams (Walton), a very stylish reachy pair of Black Reds rightly placed. Second (Morgan) very good Black Reds again. Third (Haigh) very neat Black Reds; c., Firth (Brown Reds). *Duckwings*.—*Cock and Hen* (seven).—First (Walton) a fair pair. Second (J. Smith) a moderate pair, the cock too long in wing. Third Calladine; c., Whitley. *Cockerel and Pullet* (five).—First (Walton) a reachy pair with rather too much feather. Second (Eaton) a neat pullet, but the cockerel carrying his tail too high. Third (J. Smith) smart, but the pullet

failing in colour on wing. *Black Bantams* (seventeen) were all Rosecombs, and a strong class. First (Young) neat in head, bright in colour, and clear in lobe. Second (Clapham) clear in lobe and bright in colour, but rather heavy in comb. Third (Shackleton) very good in lobe; v.h.c., Roberts, Jas. Walker, Charlton, Beanland, Rhodes; h.c., Thompson and Rawnsley. *White Bantams* (eleven) were, with the exception of two unnoticed pens, Rosecombs. First (Rawnsley) a well-known pair. Second another pair from the same yard. Third (Crowther) rather loose in carriage of wing, and a trifle heavy in comb. *Sebright* (eleven) not a wonderful class. First (Lloyd), second (Bracewell), and third (Richardson) were all good Silvers well placed. *Any Other Variety* (twelve) were mostly Piles of moderate quality, which should not, we think, have been admitted to this class. First (Walton) willow-legged Piles. Why awarded a prize in this class we fail to see; the cocks might have competed singly in the Game Bantam classes. Second (Walker) yellow-legged Piles again. Third (Walshaw) still another pair of Piles, willow-legged this time; h.c. (Crewe) Japanese, which should have stood first in our view of the matter; h.c. (Cannan) more Game, as also were Aspdon and Fell.

TURKEYS (five, with one pen empty) were all good pairs. First, Bulman; second, Braithwaite; third, Hope; h.c., Rawson.

GEESE (twelve) a good class. First (Rawson) a fine pair of Greys. Second (Snell) large Greys again. Third (Dodsworth) very large Whites; h.c., Braithwaite (Whites); Smith & Sutcliffe, and Shackleton, both Greys; c., Snell & Cannan (Whites); Atkinson (Grey).

DUCKS.—*Aylesbury* (thirteen) were a good class. First, Gunn; second, Snell; third, Mallinson. *Rouen* (fourteen) except the winners were only a moderate class. First (Newton), second (Mallinson), and third (Rawson) were all good pens very similar in merit. *Any Other Variety* (ten).—First, Gunn; second, Parkinson; and third, Bygott, were all Pekins, the first best in carriage and colour, the second failing most in carriage.

PIGEONS.—*Pouters* (six).—First (Townend) a Red Pied; second (Popplewell) a Blue Pied; third (Kirby) a White; e., Mawson. *Carriers* (six).—First, Lomax; second, Townend; and third, Thompson, all Blacks; h.c., Mawson. *Tumblers, Short-faced* (five).—First (Weston) a fine Almond; second (Weston); and third (Mawson) both Almonds also; h.c., Weston (2). *Baldhead or Bearded* (eleven).—First (Watmough) a Blue Bald. Second (R. Woods) a Blue Beard. Third (R. Woods) a Red Feather-legged Beard; v.h.c. (Lund) a Blue Beard; h.c., Watmough, Sharp, Lund; c., Cook and Beal. *Any Other Variety* (thirteen).—First (Fowler) a Red Agate. Second (R. Woods) a Yellow Agate. Third (R. Rawnsley) a Black Agate; v.h.c., Lund, R. Woods (both Red Agates); h.c., Lister (2). *Owls*.—*English* (eighteen).—First (Lister) a Silver. Second (Thresh) a Blue. Third (Rawnsley) Blue also; v.h.c., R. Woods, Thresh; h.c., Carter, Hargrave. *Jacobins* (eighteen).—First (Dale). Second (Holt). Third (Dale) all Reds; v.h.c., Kell; h.c., Collingwood, Kell, Harrison, Dale. *Trumpeters* (four).—But only one appeared—namely, first (Gatty) a Black. *Turbits* (twenty).—First (Kell) Red. Second (Kell) Blue. Third (Carver) a beautiful Silver; v.h.c., Kell; h.c., Popplewell, R. Woods, Dale, Dewhurst. *Fantails* (seventeen) were a good class, all being White. First, Collingwood; second, Laidlow; third, Beldon; h.c., Ward; c., Mawson. *Barbs* (eleven).—First (Harrison) a Black. Second (Roberts) a Black. Third (Thresh) a Dun; v.h.c., Townend (Black); h.c., Lomax, Thresh, Young. *Nuns* (eighteen).—First (Dale). Second (Mawson), and third (Townend) all Blacks; v.h.c., Lomax; h.c., Beldon, Rawnsley, Bell. *Dragoons* (eleven).—First (W. Smith) a Blue, as also were second (Shewell), and third, Close; v.h.c., Shewell, Close; h.c., Smith, King. *Antwerps*.—*Long-faced* (ten).—First (Waterhouse) a Silver Dnn. Second and third (Rawnsley) both Red Chequers; v.h.c., Ward; h.c., Lister, Cheesborough; c., Wade. *Short-faced* (twenty).—First (Waterhouse) a Red Chequer. Second (Turner) a Red Chequer. Third (Wade) a Silver Dun; v.h.c., R. Wood and Mawson (both Silver Duns), Lister (Red Chequer); h.c., Firth. *Maggies* (nineteen).—First (Walton) a Black. Second (Kell) a Red. Third (Mawson) a Yellow; v.h.c., Townend (Black), Walton (Blue); h.c., Greenhalgh, Webb, Wilson. *Archangels* (eight).—First Gatty, second Webb, third Rodgers; h.c., S. Sharp; c., Moss. *Any Other Variety* (thirteen).—First (Waterhouse) a Visor. Second (R. Woods) a Domino. Third (Beldon) a Bluetie; v.h.c., Webb, R. Woods; h.c., Gatty, King.

VARIETIES.

PROMPT PAYMENT OF PRIZE MONEY.—Mr. T. W. Anns of Clapham writes to us as follows:—"I beg to record with a great deal of pleasure the receipt from the Secretary of the Bexley Heath Poultry Show on Thursday, December 7th, of a cheque for my sale and prize money. I only wish some of the larger and older shows would take a lesson from this young and rising one."

—**DONCASTER AGRICULTURAL SOCIETY.**—The next Exhibition of this Society is fixed to take place at Doncaster on Wednesday, Thursday, and Friday, June 29th, 30th, and July 1st, 1881.

—**BELFAST POULTRY SHOW.**—We are pleased to learn that the entries for this excellently managed Show are larger than ever this year. Poultry number 415 (of which Brahmas, with eight classes,

contribute eighty). Pigeons 367, and Cage Birds 150, making a total of 932. Not bad for Ireland. The Show opened yesterday and closes to-night. We shall give a report next week.

—**MISS E. SHUTER'S DARK BRAHMAS.**—We learn that Mr. Comyns has recently added to his yards Miss E. Shuter's entire stock of Dark Brahmas. These birds have had a good share of success of late years, and we are pleased that the strain will not be lost by the retirement of Miss Shuter from the list of exhibitors. We trust this retirement may only be temporary, and that before very long we may have the pleasure of seeing Miss Shuter's name in the prize lists once more.

—**THE PRACTICAL RABBIT KEEPER**, by "CUNICULUS." (Cassell, Petter, Galpin, & Co.).—We have had this work for some time on our table. It is prepared with all the care and attention to important details which characterised the companion works on Poultry and Pigeons issued by the same firm. We can heartily recommend it to such of our readers as add Rabbits to their list of pets.

—**ARTIFICIAL INCUBATION AND THE BREEDING AND REARING OF POULTRY**, by H. TOMLINSON. (Simpkin & Marshall).—We have read this pamphlet with much interest. Being from the pen of so old a fancier as Mr. Tomlinson it could not fail to contain many valuable hints. We must, however, confess to a certain feeling of disappointment upon two points. The first of these is that the pamphlet contains no description of Mr. Tomlinson's incubator, beyond a mere general statement; and the second is that we have no details as to the system of breeding adopted by the author. We shall have occasion to refer further to the writer's remarks upon incubation in a series of papers upon this subject, which we shall commence in our new volume. The illustration drawn from Mr. Tomlinson's own prize-winners and poultry houses are perhaps the best part of the work.

—**PHEASANT POISONING.**—For some time past the keepers of the Marquis of Bath have discovered a great number of Pheasants dead on the estate. Naturally it was assumed that some persons had been laying down poison, so it was determined to send their internal organs for analysis, which, on being done, it was discovered that the birds had been poisoned from eating the shoots or leaves of the Yew tree, which are numerous in the plantations. The discovery will involve a serious consideration for those who are breeding Pheasants under the same conditions as exist at Longleat.

—**BATH AND WEST OF ENGLAND SOCIETY.**—An adjourned Council meeting was held at the Charing Cross Hotel, London, on the 8th inst. Mr. Jonathan Gray reported a correspondence which had taken place between himself and the authorities of Cardiff with reference to the Society's meeting in 1882; and the Secretary presented a letter from the Town Clerk on behalf of the Mayor and Corporation, inviting the Society to visit their borough in the year stated, and undertaking to render every possible support in bringing the Show to a successful issue. On the motion of Mr. Gray, seconded by Colonel Luttrell, it was resolved that the invitation from the Mayor and Town Council of Cardiff be accepted, and that a deputation be appointed to visit the town to inspect the proposed sites and make preliminary arrangements, subject to the approval of the January meeting of the Council of the Society.

—**BRITISH BEE-KEEPERS' ASSOCIATION.**—At the Committee meeting of this Association, present Mr. T. W. Cowan in the chair, Rev. E. Bartrum, Messrs. Cheshire, Glennie, Hooker, and Rev. H. R. Peel, Hon. Sec., the balance sheet for November was presented. The total receipts for the eleven months of 1880 being £438 15s. 1½d., and the expenditure for the same period £438 7s. 8½d. The second edition of "Modern Bee-keeping" having been completed by Mr. Cheshire was presented by the Sub-Committee, and it will pass at once into the printer's hands. The diagrams will be published by Messrs. Longman for the Association, and will be placed in the hands of the book trade at the beginning of the coming year. Some further arrangements for next year's work were considered, and February 16th was settled for the date of the next meeting.

—**ROYAL AGRICULTURAL SOCIETY.**—At the general meeting of members of this Society, the Secretary, Mr. H. M. Jenkins, read the

report of the Council, which stated that during the present year the number of Governors and members had been increased by 153, the total number now being 8082. The Carlisle meeting had been remarkably successful, notwithstanding the very unfavourable weather experienced during the last three days; and, although the receipts were not sufficient to cover the expenditure, the Council were enabled to announce that the deficit would not entail any further diminution of the funded capital of the Society, as it could be covered by the surplus ordinary income of the year. The preparations for the Derby meeting next year, which the Council had decided should commence on Wednesday, July 13th, and close on the following Monday evening, were well in hand. The Council had deemed it advisable to restrict henceforth the amount offered as prizes for live stock by the Society itself to a maximum of £3000. The Local Committee proposed to liberally supplement the Society's prize sheet. The Council had under their consideration the very serious outbreak of sheep-rot which caused so much mortality amongst the flocks of the country during the year, and have instituted a practical as well as a scientific investigation into the whole subject. They regretted to observe that foot-and-mouth disease is again prevalent in several districts, after an almost complete immunity from the disease for nearly two years. With reference to pleuro-pneumonia, the Council has the satisfaction of reporting that a considerable diminution in the number of cases, as compared with last year, has been effected by the measures adopted for its extermination.

HEATHER HONEY.

(Continued from page 473.)

It is not easy to give directions for obtaining the best results in Heather honey that shall be strictly applicable to every season and district. In purely highland regions the Clover blooms so late that there is really no interval between the two harvests; but generally it is found that there is an interval of about a fortnight, unless where the Limes bloom so late as to fill the gap. In all cases, however, the result of the earlier harvest is, except where the extractor is kept at work, to fill up the brood combs to the almost total exclusion of the queen from egg-laying. The interval, where such exists, is usually marked by the massacre of the drones—an intimation that the bees are beginning to fear the approach of times of scarcity, and that brood-rearing is no longer persevered in. To guard against this, means must be taken to ensure that no such feeling of scarcity shall exist. The gap, where it exists, must be tided over by steady but slow feeding. This feeding may not necessarily be of an extraneous nature, as the mere uncapping of portions of the sealed stores in the brood nest from day to day will admirably serve the purpose. It is perhaps not generally known that this uncapping of sealed stores is really equal to the best stimulative feeding; for it is the habit of the bees to remove all honey from cells thus damaged by the knife, and of course in doing so they are really being compelled to feed. If feeding be otherwise necessary it should be by means of honey only, so as to avoid the slightest suspicion of having sugar syrup mixed with the honey either of the brood combs or the supers, until at least the work of depriving is over for the season.

Besides securing that, either from natural or artificial sources, there shall be no period of felt-scarcity between the earlier and later harvests, it will be necessary to provide abundance of breeding room during the whole course of the season. Where hives are run for the extractor this is of course abundantly provided for; but where supers are being filled there is, as a rule, no such provision made after the supers are once in their place. The difficulty of removing supers for the purpose of manipulating the frames and the danger of crushing bees in replacing them deter most bee-keepers from the operation. But I think our supers can be so made that they can be removed and replaced almost as easily as a single frame. Instead of having our super trays constructed to hold two and even three rows of sections, they may be made to hold only one row, and instead of wooden laths their bottoms may be of angle tin, thus ensuring their being easily handled and a minimum of propolis. Such cases of sections will, besides, admit of our giving the bees super room more gradually, which is a great advantage early in the season. These trays being so placed that the sections run crosswise to the frames, it is evident that by removing any one of them a certain number of frames below may be reached without disturbing the other trays.

Whether with ease or difficulty, however, we may consider it absolutely necessary to obtain access from time to time to the frames below. Thus the directions I have formerly given as to

"spreading the brood" may be continued all through the Clover season and up to the advent of the Heather. When this time comes it will be sufficient to secure that the whole body of the hive is filled with brood and eggs, so as to compel the bees to store the Heather honey almost entirely in the supers or upper storey. Such may be regarded as general directions, but there are other ways of attaining large results in Heather honey.

Where several stocks are kept it may, for instance, be found very profitable to set aside certain hives especially for this purpose. These might, when the Heather comes in bloom, be greatly strengthened by having all frames with honey only removed, their places being filled with comb of brood from other hives stimulated for the purpose; or swarms may be added to them where such can be procured, or those that stand side by side may be united, bees and brood. In any case the golden rule of bee-keeping must now be particularly observed—"Keep all your stocks strong."

When I kept bees in the low country I was in the habit of removing them to the moors, but not having taken any special care to secure an overflowing population I did not reap any advantage to compensate for the trouble. Were I in such circumstances again I should, before removing them, drive or shake all the bees out of my weaker hives, add the brood to the others, carry them to the moors, and then run in the driven bees, dividing them according to the strength of the stocks removed. All unfinished supers would be piled on these hives, and empty ones added only if there were bees enough to crowd them: or I would, instead of supers, place on some hives an upper storey filled with frames having foundation only. In this way probably the greatest weight of Heather honey might be secured, such frames being afterwards squeezed out; for they would contain neither brood nor pollen, and extracting Heather honey once sealed is beyond the power of any machine yet made.

Friend Paterson of Struan has obtained excellent results from swarms purchased from the lowlands. These, being earlier than his own, have time to fill their hives with brood before the Heather blooms. And it may be worth the consideration of highland bee-keepers whether it would not be most profitable to work their own stocks as far as possible on the non-swarving system, and purchase swarms for increase. Mr. Paterson obviates the late-swarving difficulty in a rather ingenious way. His hives when in full strength contain about sixteen large frames. These throw large swarms, which he puts into hives contracted to ten frames or so, and at once cuts out royal cells, giving a laying queen if possible to the parent stock. His swarms crowding these smaller hives are ready for immediate supering, and the parent stock so rapidly recovers that it, too, is in the best of condition when the Heather comes on. As there are few districts in our country where it is not possible to remove bees to the Heather, I venture to hope that this subject may be widely taken up; and if a few of those who have had more experience of it than myself would come forward and state the results of such experience, it would be the easier to frame a code of rules bearing on the matter.—WILLIAM RAITT, *Blairgowrie*.

COMB DESTROYERS.

WAXMOTHS, GALLERIDÆ, WAX MITE.—Upon turning up a skep it is quite usual to find upon that part of it which rests upon the floorboard a few small whitish caterpillars about two-thirds of an inch in length; these are the larvæ of wax moths, of which not unfrequently more than one species are present. A further search will generally be rewarded (?) by the discovery of some small white baggy cocoons under the protection of which the chrysalids of the same insects are passing towards moth-hood. These creatures are only capable of working serious mischief to the bee itself where the latter is in the hands of the ignorant or negligent; but they should nevertheless in all cases be diligently sought out and mercilessly destroyed, as stock combs—i.e., combs removed and kept in store for future use, are liable to be wrecked by them even after due precautions have been taken.

On a moonlight night in the warmer weather the female *Galleria* may commonly be seen flitting rapidly about the hive door in order to gain admission, so that her eggs may be deposited on the combs; or she, having been baffled by the guards, may be noted seeking some crevice in the hive itself as the best "opening in life" which she can obtain for her prospective young ones. The bees, with that instinct which as much outleaps our comprehension as it excites our astonishment, appear perfectly to understand that the exclusion of the *Galleria* is a necessity of their well-being; but the nocturnal moth has in the gloom an advantage over the defenders, for the former, a night-flying insect, can see much more clearly in a very weak light than can the bees. If a

moth be dropped into a hive "the rapid dispatch" that it receives at once tells the tale of the fate of those that are grasped as they run the gauntlet. An entrance is, however, gained, sometimes even in strong and often in weak hives. The moth within with wondrous quickness deposits the eggs, from which in three or four days in a warm temperature emerge minute grubs, the first care of which is to spin over themselves tubes of gossamer, from which the head protrudes, and the work of eating the material of the comb at once begins. These larvæ are of dirty white colour, and have very long characteristic bristles standing out from their sides much like cats' "smellers" in general arrangement. These bristles retain the insect in the centre of its tube-like web, and not only act as a protection in preventing the bees from getting directly at it, but hold it in the tube, even if the direction of the latter be perpendicular, without any effort on the insect's part. These hairs, nevertheless, admit of easy progression by that segmental contraction which all must have noticed in the caterpillar. Those that find their quarters on the floor do but little mischief, as they reach out after the débris of wax scales and cappings, always dropping in a hive in which breeding is in rapid progress, and the necessary comb-cleaning and repairing produces a shower of chips which provides them all necessary sustenance. But the case is far different with those tunnelling in the very midrib of the combs; as they progress, their covering tube is elongated, while into its fibres are worked the dejectamenta of the insect itself. They seek out pollen cells and bore at their base, and pass through and destroy many of the grubs, if they do not actually eat any part of those that lie in their path. The bees find difficulties, as we have already seen, in removing the creatures protected by their web-like trail; but in strong colonies where all the combs are peopled, the grubs are promptly discovered and cut bodily out, repair quickly following their ejection. It is only in weak, queenless, or discouraged stocks that the wax moth has a chance of working much mischief; but here often it will so carve and weaken the combs that they will fall and become a complete prey to the invader, which will ere long bring them to a shapeless mass of grubs, cocoons, débris, trail-web, and uncleanness. From what has been seen it is clear that the cure for the wax moth is "strong stocks," while combs removed from the bees must, in the absence of their natural defenders, receive some protection. Combs exposed to a freezing temperature will have the eggs of *Galleridæ* within them destroyed, while the fumes of sulphur will have the same effect. They should now be well covered in a box until the season has advanced too far for the moth to be abroad, when all will go well. Combs partially destroyed may yet be of assistance to a swarm, but in this case all webs should be cut out. Those who know the value of foundation will not, however, be likely to adopt this course.

After three-weeks feeding the grub discontinues eating, and seeks a place of safety in which it may build its shroud and await its transformation. It would appear that the time passed as a chrysalis greatly varies according to the temperature and season, those spinning late in autumn remaining as nymphs the whole of the winter. It is thus fortunate that they are not produced at the time the bees are unable to act on the defensive.

Besides the wax moth, comb, especially if it have about it some nitrogenous matter, is liable to be attacked by one of the *Acaridæ*. They sometimes locate themselves in comb honeyput by for market, and work sad mischief. Their presence may be known by a collection of dirty yellowish coarse dust, looking not unlike the result of the labours of the cheese mite. If this be examined microscopically it will be found to consist of dejectamenta, comb-scrapings, and exuviae crammed with the insects in various stages. They are, of course, produced from eggs, and have at first—*i.e.*, in their larval stage, six legs only, but after five or six moults these have increased to eight perfectly developed ones. The abdomen is unsegmented, and very long bristle-like hairs keep the insects sufficiently free of the mass in which they pass their existence. They are nearly colourless, and when fully grown measure about the one-fiftieth of an inch in length. Some specimens of abnormal combs which I valued have unfortunately been considerably injured by this *Acarus*.—F. CHESHIRE, *Avenue House, Acton*.

IMPROVED STRAW HIVES.

ON page 474 "A. P." suggests some improvements in the straw hive so that comb foundation may be used in them. This may be accomplished by constructing them on the Stewarton principle. I think that no straw hive should have a fixed top. I made one with the top separate, and secured it to the sides with string. I could then take out the comb with the greatest ease without breaking it by turning the hive on its crown, cutting the string, removing the cross sticks, running a knife round the sides, then lifting off the hive, separating the comb from the crown, and

letting the comb recline on a dish held by the side of it. There is no occasion to touch the comb with the hands when emptying the hive. This moveable top then suggested the double straw hive. I made another 15 inches wide inside that would fit in it, thus forming a hive with a double wall. The bees in this hive swarmed ten days sooner than my other two, which I attribute to its being warmer, as the others had only covering on the top. It can be used as two hives in the summer.

The next step was to make a bar-frame straw hive 16½ inches wide, holding five frames 14 by 7 inches. This hive is in two parts. Where the frames are it is 8 inches deep, the top part being 4 inches when fixed together. I call it the improved Pettigrew hive 16½ inches by 12 inches. The season being so bad here in Yorkshire, a first swarm has only filled the frames and one side of the bottom part of the hive. The top part I have filled with warm material. The other I have made is a bar-frame hive. The frames are 14 by 9 inches. It holds five frames; the side combs are also moveable. This hive I have tried with natural foundation, as I have no artificial. The mode adopted in fixing is very simple. The joiner made the top bars with a groove a quarter of an inch wide and deep. One side of the groove is in the centre of the bar. I placed the foundation in the groove and fastened it with a strip of wood three-sixteenths of an inch square, with one corner taken off to act as a wedge. It answered admirably. Those who would like to try comb foundation in these straw hives should try this plan with bars. After the foundation is fixed in the bars secure them in the crown of the hive at the proper distance.—A GARDENER.

REMARKS.

- 5th.—Mild with good deal of cloud; sunshine at intervals, and very fine sunset.
- 6th.—Fine pleasant spring-like day.
- 7th.—Cloudy; not much sun; fair and mild.
- 8th.—Fair but overcast; rather cold wind.
- 9th.—Fine and mild sunshine in forenoon; moonlight night.
- 10th.—Slightly overcast in middle of day, otherwise very fine and mild with bright sunshine; lunar halo 11 P.M.
- 11th.—Fair and much colder with good deal of cloud; bright moonlight evening. Extraordinarily mild, the temperature about the same as the average of October, and actually warmer than some weeks in October of this year. Barometer very high and no rain.—G. J. SYMONS.

COVENT GARDEN MARKET.—DECEMBER 15.

Large arrivals of Canadian Apples this week, but the fruit has been seriously injured by frost, consequently much has been sold at a heavy loss. Trade very quiet, with a demand for good samples of Grapes only.

CHRISTMAS.

"Deck the walls with Holly! welcome fun and frolic!
 Ever when December comes to sadness bid adieu
 Cold the winds and cruel; pile the fire with fuel;
 Eagerly to Christmas give a greeting warm and true."

STRONG faith have I in the virtue of a good hearty laugh as a promoter of health both of mind and body. What more fitting, then, to dispel the gloom of short days and murky skies, to cheer the sadness inseparable from the last days of the dying year, than the bright time-honoured festival of Christmas?

From how many sources and from what a variety of things does it derive its brightness! As year after year glides away, and the hand of Time lays a firmer grasp upon us, the mind develops a growing tendency to retrospective views of the sunshine and shadow that chequer the swiftly fleeting days of our lives; and those of us who wisely resolve to take bright and cheerful views of things, know full well that sadness and sorrow come to all of us sooner or later with such depressing effect as would be difficult to encounter were it not for the cherished feeling of hopefully looking forward that has become inherent in our nature. Well, then, for this especial reason, as well as for many others, we hail the coming of Christmas once again, and make especial preparation to enjoy it as a time of family gatherings, of genial social intercourse that shall witness a strengthening of old friendships and the beginning of new; for Christmas is the sworn enemy of selfishness, and a true promoter of kindly feeling.

One of the brightest Christmas features is wanting this year—we have no berried Holly. In the woods here Holly abounds; there are several thousands of trees but hardly a berry, much to our regret, for we have no substitute for it, and shall miss the gay effect of the bright scarlet berries both in our church decorations and our houses. The birds will miss them still more should the soil become frostbound for any length of time, and they are driven to seek food among the hedgerows and shrubs. *Iris foetidissima* has an abundant crop of its pods of scarlet berries, with which much may be done to atone for the barrenness of the Holly. In skilful hands this *Iris* is one of our most valuable hardy plants for decorative purposes. The pods are borne in clusters upon the ends of long stems springing out of and well above the long dark green flag-like foliage, over which the weight of the fruit causes them to bend gracefully. When used in decoration we have only to copy Nature to be successful, arranging its foliage in pans of damp sand with the berry-bearing stems disposed among them

precisely as they grow. But it is not merely for our Christmas decorations that we regret the scarcity of Holly berries. Many a poor family will be robbed of the humble Christmas feast, for which the sale of Holly usually affords the means, as it often passes through the hands of two or three keen dealers before it reaches the London or Brighton markets. It is indigenous to the soil of this part of Sussex, and is usually collected from the woods and the hedgerows of garden and field, as well as from the thousands of bushes on the wild waste lands of Ashdown Forest, so that the labourer may contribute his bundle or two, and the small farmer his cartload to swell the huge waggonloads which are usually seen proceeding Londonwards along the main roads tending in that direction. Occasionally some adventurous spirit, having collected enough of an unusually choice kind to load his market cart or van, has set off with it to Covent Garden, a distance of from thirty to forty miles, and will long afterwards proudly tell of the adventures and result of the journey. More than once has a certain shrewd man told me how he refused £5 for his cartload, and cleared 30s. more by selling it in small quantities.

Mistletoe is not at all common in this neighbourhood, nor have I ever seen such clusters of it in Sussex as there used to be upon the grand old Apple trees in the orchard at Provender near Faversham. No pruning of root or branch they ever had, and yet for several generations they had borne Apples and Mistletoe in more than sufficient abundance for the wants of a large family. A single tree would often yield twenty bushels of fruit, so that a few failures had very little effect upon the regular supply. The old trees were always as attractive at this season of the year, with their huge mossy boles and large Mistletoe boughs, as they were in spring with their thousands of pink-tipped blossoms, and in autumn with their rosy-cheeked Pearmaines or yellow Golden Pippins, some of which were always kept in reserve to be roasted for the wassail bowl on Christmas eve. Such trees are not common, nor dare I venture to advocate the planting of standards; but my object in mentioning them is to try and induce everybody to introduce something more than trim keeping and high culture into their gardens—to impart features of lasting interest, objects of perennial beauty, elegant or picturesque, that cling to the mind and are cherished there among many a sunny memory and dear association. Plants and trees of an ordinary type do not usually effect this, and yet many of those which we recall are neither very "rich nor rare." The Cork Tree at Linton, the Tulip Tree at The Mote, the Beeches at Chatsworth, the Traveller's Joy at Pentillie Castle, the Spanish Chestnuts at Maresfield Park, the Scarlet Oaks at Alton Towers, the Lueombe Oaks at Carclew, the Ash trees at Pencarrow, the *Pinus insignis* at Lamorran, are all sunny memories upon which we love to dwell. But I must not further indulge in what to me are pleasant reminiscences, but will conclude with a hope that pleasant thoughts and happy moments may be fully enjoyed by every reader of the Journal as they are spending

"A MERRY CHRISTMAS."

—EDWARD LUCKHURST.

SAWDUST FOR PROPAGATING.

IN reply to your correspondent "KITCHEN GARDENER," I have to say that all plants rooted in sawdust here have taken with singular rapidity to any soil or mixture of soils in which they

have been potted. They root very quickly and surely, forming a whorl of strong roots, from which the dust is easily dislodged by a tap or two on the stem of the cuttings. When this does not do it they are rinsed in tepid water. It may be stated that we have a good command of bottom heat, and that the dust is laid firmly on the slates to the depth of 4 inches and is kept constantly saturated with water. To-day (December 7th) we have inserted cuttings of *Nepenthes sanguinea*—not to be risked in any uncertain quarters—and *Dracæna Goldieana*, all in sawdust fresh from the mill.

We also use sawdust for plunging Pines in over heated chambers, and were to-day clearing out a house of Pines, from which we have been cutting fruit for the last two months. The dust we are turning out was placed in the pit the winter of 1878, and we find it so fresh and free from fungi that, were it not that we had brought forward fresh dust, we should have continued employing it for another year. No other plunging material is so clean, free from woodlice and worms, and none so easily plunged in. Not only so, but the Pine roots were found rooted through the pots into it, and we never before saw such a network of roots as were the balls: they looked like a ball of living fibre. If there is an objection to the dust for this purpose it is that it becomes rather dry; but any evil consequences arising from this condition we counteract by causing the water to run well over the rims of the pots when they are watered. This keeps the dust round the pots quite damp. The best swelled Pine for its size we ever grew was in this bed. It was cut fourteen days ago, was seven pips deep, and weighed 8 lbs. all but one ounce, while others were 8 lbs. and one 9 lbs., all in 11-inch pots, and cut within the last month. With a good command of bottom heat we should never think of going far afield for spent bark or cocoa-nut fibre for plunging Pines in if sawdust could be had, and it can easily be obtained by anyone near a sawmill. That used here is from fresh larch, spruce, Scotch fir, oak, ash, &c., all mixed together.—D. THOMSON, *Drumlanrig*.

ASPARAGUS FAILURE.

MR. IGGULDEN will be surprised when I tell him that the garden where I grew my Asparagus is not drained at all except the walks, where the drains are 5 feet deep. I have misled him by saying the ground selected was wet. I should have said that the water takes a long time in percolating through the ground in wet weather, and the district is a wet one. The garden slopes towards the east, and at the lowest portion there is a nearly perpendicular fall of 25 feet into a valley. I have never found the subsoil waterlogged, but when the soil is wet it cannot be worked. It is ridged in winter and forked down in spring as wanted, and most of the garden receives every winter a dressing of screened ashes. Lime is applied when I think it is required.

The Asparagus borders, with clinkers for drainage, I made nineteen years ago, and the last Asparagus beds I dug up on the 1st of July, 1878. I then commenced preparing for growing Asparagus on the French system, the distance being 3 feet from plant to plant and 4 feet between the rows. The depth of soil in the Asparagus border was about 2 feet. No shale or subsoil while trenching is going on is ever brought to the surface on any account. The subsoil is broken up as deeply as a man can drive his pick in; it remains at the bottom of the trench, and is covered with manure. I have discontinued the use of salt for many years as a top-dressing for Asparagus beds, as I found it rendered the beds too wet. Seaweed I consider the best of all material for top-dressing Asparagus beds on light sandy soil. I thank Mr. Iggulden for his courteous reply, which I have read with great interest.—JOHN NUNNS, *Wimbledon*.

GALVANISED WIRE AND FRUIT TREES.

MANY letters were published on this subject in the last volume of the *Journal of Horticulture*, and the opinions of correspondents were so widely divergent that I was requested by Dr. Hogg to examine the whole question, and to conduct some experiments, with the object, if possible, of finding a basis on which the views of the different writers are reconcilable. Until the late discussion there were many, and amongst them horticulturists of high repute, who entertained the opinion that galvanised wire was not injurious to fruit trees. This opinion was founded on experience, and those who had employed the wire successfully for more than a quarter of a century had reasonable grounds for the conclusion they arrived at on the subject. For a number of years I have had experience with this wire in gardens, and I have never until the present year perceived the slightest injury to the shoots or branches of fruit trees when in contact with it. Like "C. P. P.," I attributed the injury that was experienced by others to too tight tying

or abrasion. That injury has resulted from mistakes or accidents in these respects cannot be doubted, but I am now perfectly convinced that they are quite inadequate to account for the serious damage that has occurred to trees under the charge of skilled and careful gardeners. Mr. Long of Wakefield and Mr. Simpson of Wortley, among others, adduced evidence to the effect that shoots of Peach trees that were not tied at all, but which simply rested on the wire, were injured. I have found the same results in some carefully conducted experiments, and I must dismiss the tight-tying and abrasion theory as quite insufficient to account for the evil in question.

An Essex correspondent attributed the recorded instances of injury to frost in combination with unripe wood, as such wood was affected when in contact with cold iron, and that paint or any covering to the iron was remedial in proportion to its non-conductibility. Against this theory Mr. Simpson gave a reply that was conclusive, for the trees under his charge were ruined in a house which the frost did not enter, as was proved by the preservation of tender plants in the structure; also trees that had been secured to well-painted galvanised wire and unpainted copper wire for a dozen years had received no injury whatever. Mr. Long sent examples of wood to the Editors, some of which had been injured in winter and some in summer, the latter being the worst. Mr. Crowley of Croydon found that most if not all the injury was done in summer, the foliage and tendrils of Vines turning black when they touched the wire. I also had negative proof last winter, and positive proof this summer, that extreme cold is not the cause of the evil. I visited a garden in which the mercury of the thermometer fell below zero on several nights, and after minute examination I could not find a trace of injury to any portion of the fruit trees that were secured to unpainted galvanised wire, although some of the fruit spurs were killed by the frost. That is what I call negative proof. The positive proof is that the laterals of Vines under glass which I attached to some wire in June were very seriously injured during the summer months; in fact the damage they sustained in six weeks, ending with the close of July, was far greater than they have sustained in twice the time that has elapsed since. The evidence, therefore, against the "cold" theory is overwhelming.

Mr. Wm. Taylor contributed an excellent and suggestive letter in an endeavour to aid in the solution of the problem. Zinc he recognised as a very sensitive metal, and might be acted on by some water so as to render it noxious to vegetation. He adduced evidence of zinc shortly rendering water undrinkable, and also hinted that the rain falling through an impure atmosphere might bring down a chemical agent on the zinc and render it noxious to vegetation. I thank Mr. Taylor for that hint, for a reason that will be hereafter stated. Although this correspondent had galvanised wire obtained from different sources, yet in no case had it proved injurious; therefore the pure water of Longleat, even when in contact with zinc, is not dangerous to vegetation. But Mr. Woodcock of Sheffield adduced striking proof of the effect of the water of that town on zinc, which crumbled off the wire like powder after having been kept moist for a week. It is noticeable, too, that in and near that town injury to Peach trees has been very severe, and much galvanised wire has had to be painted to save the trees. It is not at all improbable that some water employed for syringing may have had an injurious effect in combination with the zinc on the wire, yet I have this summer found decided injury result to Vines that have never been syringed.

Another correspondent, "T. H.," states that Vines and Peach shoots, also Melons and Cucumbers, trained to well-painted galvanised wire sustained no injury whatever, but when some new wire was put up and not painted it "attracted the lightning," and great damage resulted to the growths in contact with the wire. Another writer takes this view of the case, for he states the trees have suffered so much that all the wire has been thickly painted to "prevent injury by electricity." This view of the question may be worth a little examination, yet at the same time a formidable difficulty arises at the outset—namely, electricity is not a local agent, while the injury resulting from the use of the wire is certainly not general, but on the contrary, as I shall be able to show, is to a very marked extent local.

It is generally admitted that electricity is universal as an agent of great force affecting all kinds of matter. Dr. Franklin supposed that all terrestrial subjects were pervaded with electricity; but if the equilibrium were destroyed, as it is by a variety of causes, one part of the excited body, the positive, contained more than its natural quantity of electricity, and the other part less—the negative. When one body positively and another negatively electrified are connected by a conducting substance, the electricity passes from the positive to the negative body and the equilibrium is restored. Granting for the sake of argument that the branch

of a Peach tree is the negative body, and something, it matters not what, to which the wire that touches it is connected, is the positive body, it seems to follow that the electricity would pass to the Peach branch to restore the equilibrium, and, as many think, cause injury. If the current is powerful enough it would no doubt cause injury, as is the case with lightning; but is it sufficiently powerful? I think not, and it is beyond all doubt not general, as it must be to sustain the theory. But that is not all. Oxidation appears to be of great importance in the excitation of electricity both by friction and in the voltaic battery. Now let us look at the Peach trellis. In all the communications re-

ferring to this subject it is the new unoxidised wire that is stated to be the most injurious, the old or oxidised wire having little or no deleterious effect on the trees. That this is really so I shall be able to adduce pretty conclusive proof. The electricity theory, therefore, fails on the two important principles that ought to sustain it—1, Electricity is universal, while the injury supposed to be connected with it is only local; 2, Injury does not follow where the wire is much oxidised, while oxidation is essential to the excitation of electricity.

This subject is alluded to more fully because I have received several private letters, the writers of which agree with those

Fig. 101.—*DRACÆNA TELLINGII*.

published that the evil in question is caused by electricity. The question now stands thus—the tight tying or abrasion theory fails; the cold theory fails; the electricity theory fails, and we must look in another direction for a solution of the problem.—
J. WRIGHT. (To be continued.)

DRACÆNA TELLINGII.

THE narrow-leaved *Dracænas*, so well suited to table decoration, were referred to on page 527; and the other type—namely, those possessing broad leaves and a bold effective habit—now merit some description. These are admirably adapted for general decorative purposes, and when well grown and the foliage highly

coloured there are no plants more imposing, either in groups or singly. As in the other section, we owe several of the best forms to Mr. Bause's skill in hybridising, and the one represented in the engraving (fig. 101), kindly supplied to us by the General Horticultural Company, is scarcely excelled in attractiveness by any other in commerce. The specimen from which the drawing was prepared not only possesses all the distinctive characters of the variety, but also indicates what can be obtained by skilful culture, and is a fair representative of the *Dracænas* grown at the Melbourne Nurseries, Anerley.

D. Tellingii is the result of a cross between *D. ferrea* and *D. regina*, but is strikingly distinct from and superior to both parents. It is of bold, erect, and vigorous habit, with large elliptical or

oblong leaves, about 6 inches in breadth, and strongly recurved at the points, in the style of *D. voluta*. The colour is a deep bronzy green with a rosy margin, becoming crimson in the older leaves, and the stout leafstalks are similarly coloured. In addition to these qualities the firm thick texture of the foliage renders the plant more than ordinarily durable—a character of inestimable value as regards its employment for the decoration of houses. Six as handsome *Dracænas* as could be desired of the type under consideration is the subject of the engraving, *D. Knausei*, *D. Barrovi*, *D. Gladstonei*, *D. Elizabethæ*, and *D. Imperator*.

HARDY FRUITS—PEARS AND APPLES.

As an old fruit-grower I have been greatly interested in the articles which have recently appeared in your paper, especially those by "WILTSHIRE RECTOR," Mr. Luckhurst, and "CHESHIRE RECTOR." The report of Mr. Luckhurst on thirty-six varieties or more of Pears during the past season cannot fail to be highly instructive to the willing learner.

I grow most of those Pears, and several others also, and I am glad to have the opportunity of comparing the experience of other gardeners or amateurs with my own. It is, however, important in all fruit-growing to bear in mind the effects of locality and soil on the produce. Take, for instance, that beautiful Pear the Chaumontel. In Mr. Rivers' catalogue it is stated that in some gardens it is little better than a baking Pear when grown as a standard. "It evidently requires the warm sea air." Judge of my surprise when asking a neighbour of mine, a lady who with her husband takes a great interest in her garden, which was her favourite Pear of all they grew. She replied, The Chaumontel. But, I asked, "Can you depend upon a crop?" knowing that in spite of the high authority which declared warm sea air to be necessary for it, this Pear was grown by my friends in a garden as an espalier many feet above the sea in dry mountain air—in short, on the eastern slope of the Malvern Hills. The lady replied that they generally had a crop, and she attributed it partly to the precaution that was taken of giving the trees while in bloom, and especially if frost appeared to be coming, a bucketful each of hot water after sunset. There grew in this garden of my friends two years ago a Pear tree, standard or pyramid, the fruit of which was to my taste the richest I ever met with. I was not singular in my choice, for the dozen fruits which were sent me as a present, together with several varieties that were familiar to me, were quickly selected from all by members of my family, who unanimously declared them to be the best they ever tasted. The varieties with which they were mixed included Marie Louise, Pitmaston Duchess, the Lemon Beurré, the Pine Pear, Seckle, and others ripening about the same date—November. Unfortunately all the dozen but one were consumed before I thought of learning the name of this treasure. Its shape was between that of an Orange and a Lemon, and it had the peculiarity of being somewhat evenly divided on the surface into segments like a Melon—not, of course, so deeply or evenly marked as that might imply, but this description illustrates my meaning.

Last year I visited my friend's garden too late, and this year too early, to discover the fruit and make out its name, but I have obtained grafts of all his best Pears, and they are becoming strong enough to fruit ere long, when I shall carefully watch the fruits. The only specimen that I saved I took to Mr. Smith of Worcester, and his foreman of the fruit department could not name it with any certainty, but thought it resembled Zéphirin Grégoire. I purchased several trees of this kind, one with numerous buds, and fruited it, but unfortunately the Pears were stunted and of a different shape from the curious specimen which I have described.

One of my friends, an enthusiastic admirer of Gansel's Bergamot, declared it must be of that variety. My friend, however, has no wall for his Pears; all are standards, pyramids, or espaliers, and most persons seem to agree that Gansel's Bergamot will only succeed against a wall. If any of your readers can suggest what this Pear can be I shall be deeply grateful. I should be very glad also to know the experience of others with regard to Knight's Monarch and Beurré Rance. I have healthy trees which I have had in Cheshire, Warwickshire, and now in Worcestershire. They have never fruited with me. They are pyramids, and I believe on the Quince.

I was in London last month, and on passing through Covent Garden Market and to some of the fruit shops at the West End I tasted both Pears and Apples. Decidedly the best Pear at the time—about November 28th—was the Chaumontel. In this selection I was supported by five friends. If it had been only a trifle more melting it would have been perfect. In flavour, and juiciness, and size it was everything that could be desired.

In a shop in the West End I saw a round basket of Apples beautifully displayed. They were ticketed "Calville Apple." They were, to use the expression of my gardener, "pretty as paint," of a rich semi-transparent golden pink, and the modest price asked was 1s. each. As the finest Newtown Pippins were on sale in the same shop for less than half the money I was curious to learn why these should command so high a price. I was politely informed that they were greatly esteemed at dessert, and having to be brought from the south of France the carriage was expensive. I thought how it would gladden the hearts of my parishioners in Worcestershire if they could sell Apples for 1s. each, and I carefully brought the name, and also bought a single fruit to show to my neighbours. I see English catalogues describe the Calville Blanche as an Apple for tarts unless grown under glass, when it becomes a first-class dessert fruit. Surely it would pay to grow it in this country under glass, and it would be not only more profitable but a more certain crop than Peaches or some other fruits.

A word about an Apple called The Malster. "CHESHIRE RECTOR" describes this in your issue of, I think, December 2nd, as hardly inferior to the Newtown Pippin. As I look upon this American Apple as the *ne plus ultra* up to the present time I turned immediately after reading the Journal to the "Fruit Manual" to see the description of it. No such Apple as Malster appears in that book. That which I possess is the fourth edition, published 1875, and which I have usually found so full and complete. I turned to catalogues. In several it is omitted, unless it has some synonym which I do not know. At last I found it. The description is not inviting for a rival of Newtown Pippin. Here it is—"Malster, K.D., large-sized, greenish, of good quality, either for cooking or eating, and will keep well until January." This is only feeble praise compared with that given to many others in the same catalogue. I shall certainly try this Apple, and hope it will answer the high opinion expressed of it. Is it known by any other name?

One more Apple I will allude to—the Ribston Pearmain. It is described as having the true Ribston flavour and tender flesh. If this Apple really answers its description it will prove a valuable acquisition. Have any of your readers tried it? I intend to do so, and if you will allow me, to report on results.—WORCESTERSHIRE VICAR.

THE BEST TEA ROSE.

WE grow many Tea Roses here, and we are annually increasing the stock, which affords an opportunity of comparing the merits of different varieties at all times of the year, and for a perpetual bloomer of the finest description there is none to equal Niphetos. Some of our plants of it produced a constant succession of buds since last December, and they are growing and budding now in a cool house as if it was June. This is their continual habit—they never rest or stop growing or flowering. The buds are of that choice creamy white colour, and long, tapering, delicate shape which please all arrangers of cut flowers. Next time I plant a dozen Tea Roses half of them will be Niphetos, and I shall always employ them in this proportion.—J. MUIR, *Margam*.

CHAPTERS ON INSECTS FOR GARDENERS.—No. 16. NEW SERIES.

TO the young student of natural history, and to some of our gardeners who take an interest in entomology, the circumstance is notably singular, that some larvæ attain their full size with rapidity, while others are very tardy in their growth. The huge caterpillar of the Privet Hawk Moth is ready to become a pupa in nine or ten weeks after it has chipped the egg-shell, and there are other similar instances amongst the Lepidoptera. But beetle grubs not a few, which live concealed in wood or earth, require two or three years to pass before they enter on their period of quiescence. Hence, in the case of some species the history may at first seem perplexing. Take a species that occupies three years to complete its growth—that is, eggs deposited in 1877 produce perfect beetles in 1880, we might then assume that beetles come forth only triennially. It is not so actually, because in any particular year we should discover larvæ of various stages, and each year a brood is produced, in numbers varying doubtless according to the weather and other influences.

The duration of life sometimes shows considerable differences in the same division of beetles. We have noticed the hard-bodied beetles, such as the Elaters in the division Priocerata, and these are generally longer-lived than the soft-bodied species called the Aprosterni, a few of which we now mention. Many of these beetles are both abundant and conspicuous in gardens, and as a group they may be spoken of favourably, since they are rather

serviceable than mischievous like their tough-hided brethren. The "soldiers" and "sailors" do not leap in the manner of the skipjacks, but they run rapidly up the stems and over the leaves. They are popularly named, not very appropriately from their colours; the "soldiers" having reddish-yellow wing-cases and paler legs, the "sailors" black or bluish-black wing-cases and red legs. These belong to the genus *Telephorus*, of which there are about twenty British species. Their soft structure is, however, not an indication of pacific habits, for the beetles are carnivorous in habit, and should two of them meet they will engage each other. Occasionally the combat is carried on until the weaker is conquered and then devoured, but more frequently after a scuffle they separate to seek prey more to their appetite. They feed particularly upon the smaller insects that haunt flowers during the summer. Some of the larvæ are unknown, but those that have been discovered live under the earth, feeding upon worms and small slugs from September to April, when they enter the pupal state.

The curious and rather local glow-worm (*Lampyrus noctiluca*, fig. 102) is fond of sheltered and humid places, such as lanes near woods. In gardens this insect might be encouraged for the useful habits of the larva; but it is not easy to establish a colony of glow-worms, and several failures have been reported. The female is a larva-like creature with neither wings nor wing-cases, and it emits a greenish blue light, the nature of which is still doubtful. This is certain, that it is under the control of the insect. The male, which has wings and flies at eventide, possesses two minute luminous dots on the head. The larva of the glow-worm also sheds a light, feeble than that of the female beetle, but which upsets the absurd theory that the latter wingless insect has this luminosity in order that the male beetle may discover it. At the tail of the glow-worm larva is an appendage like a foot when it is partly drawn in. When thrust fully out it appears as a brush, and it is used by the larva to clear itself from the slime of the snails upon which it feeds; and since this larva makes an especial attack upon these in the spring just about the breeding time, it must have an influence upon their multiplication wherever the glow-worm occurs commonly.

The beetles of the genus *Clerus* are small and elegant, clothed with fine down, and rather harder than the preceding. One species calls for a remark in passing. This is *C. apiarius*, also known as the Hive Beetle, half an inch long, with a blue head and reddish wing-cases crossed by three blue lines. Though sometimes resorting to the nests of wild bees, the beetles prefer to enter hives, where they deposit eggs; and the newly hatched larvæ bore into the comb, where they seize upon the bee grubs that are attainable. Luckily, however, it is not an abundant species. The larvæ are no doubt occasionally killed by the bees, though the shell of the beetles is elastic enough to throw off their stings. Last in this group come the retiring but busy beetles of the genus *Anobium*, to one or two species of which has been attached the ominous title of "death watches," from a ticking noise produced by them while carrying on their operations in wood. This peculiar sound some ears fail to catch, hence sceptics have denied that these beetles are vocal; but the fact is unquestionable, though the omen which superstition links to it is ridiculous. It is not the gnawing operations of the insect that cause the ticking noise—that this is a call from one to another is now generally believed; and to make it, the beetles strike with their heads against some hard substance. Larvæ, pupæ, and beetles may all be found together in decaying wood; and as some of the species like variety in diet there will now and then be discovered in our seed drawers specimens of these, which, if not duly routed out, may increase to become troublesome.

The next section of beetles, the Heteromera, "unequal-jointed"—that is, with five joints to the tarsi of the front legs and the middle pair, and four joints to those of the hind pair. Their antennæ are also "moniliform," resembling strung beads in miniature. In this section we do not discover a large number of native species, yet in it are some very observable species. It divides again into two groups, the species having a neck—*Trachelia*, and those having no neck, or the *Atrachelia*. The former

have not only the hind part of the head fully exposed to view, but also possess soft or flexible wing-cases, as in the familiar oil-beetle (*Meloe cicatricosus*), a slow-moving creature with a bulky abdomen, and of a steely blue tint, showing also a propensity to exude a fluid that is oily from the joints of the legs. This insect and others of the genus resort to flowers upon heaths or in hedge-rows; when they enter gardens, as they occasionally do, they are apt to excite apprehensions which are needless, for in feeding they do but little harm to either leaves or flowers. The larvæ are believed to live as parasites in the nests of wild bees—at least after a while, for the parent beetles deposit their eggs upon or near plants, up which the young larvæ climb when they have gained sufficient strength. With singular instinct they manage to cling to the bodies of the bees when they are visiting flowers, and are thus carried by them to their nests, where they eat the pollen or honey stored by the bees for their own progeny. It has not been ascertained whether the *Meloe* larvæ ever get into our hives.

Rhipiphorus paradoxus is the name given to a small beetle, long regarded as a *paradox*, because naturalists could not imagine why specimens occurred near wasps' nests. It has a black head with black wing-cases more or less tinged with yellow, and a black thorax which is humped. The male has a pair of beautifully feathered antennæ. Recent observations prove that the larvæ live amongst the cells where the wasps nurse their larvæ or

Fig. 102.—Male Glow-worm on the wing, females and larvæ seeking food.

grubs, upon which the beetle larvæ subsist, so that they assist in keeping down these troublesome visitants to our fruits. *Pyrochoa coccinea* is another beetle that is made conspicuous by its colouring—blackish in front, and a deep scarlet on the thorax and wing-cases, hence it has received the name of the "Cardinal." The perfect beetle is often seen amongst Ferns, while the larva has its abode in old Willows or Sallows. The Blistering Beetle (*Cantharis vesicatoria*) belongs to this division, a species rare in England, and though of use in medicine, is an injurious insect to gardens where it is plentiful.—J. R. S. C.

TOMATOES AT THE WEST LYNN VINEYARD.

WHEN passing through the houses of Mr. S. Castle the other day I was surprised to see the splendid crop of Tomatoes still hanging in various stages. Mr. S. Castle evidently understands the principles of Tomato culture; he informed me that from the same plants, which have been fruiting since the commencement of the season, he has cut upwards of a ton weight of ripe fruits.

The plants are trained up the back wall of a vinery, and also to wires fixed perpendicularly along the centre beds in this and other houses. They are planted in loam with an admixture of brick rubble, and have been watered occasionally with liquid manure. Mr. S. Castle, however, attributes his success to the naturally rich

soil employed, which he obtains from land adjoining the houses. He prefers the single-stem method of training, although several of the plants along the wall have been allowed to retain two, and in some cases three shoots. The plants with only one stem are from 10 to 12 feet in height, and bunches of fruit have been cut from them weighing from 2 to 4 lbs., and single fruits weighing more than a pound have been frequently cut. One house is filled with young plants about 3 feet high just commencing to bloom, and these are expected to maintain a supply until the main crop begins next season. The variety most grown is the Old Red; a house filled with Stamfordian proved a complete failure.

The majority of the Vines, which share the houses with the Tomatoes and show the same good management, were only planted in the spring of the present year, yet they have each carried one to two bunches of good size, and the wood is strong and perfectly ripened.

A house of Cucumbers attracts notice. The plants are now coming into bearing, and are remarkably healthy and strong. Judging from present appearances they will no doubt well repay for the skilled labour and excellent attention bestowed on them. —VISITOR.

OXFORD BOTANIC GARDEN.—No. 4.

MANY other aquatic plants occupied the same tank as the Nymphaeas, some very rare in cultivation, or marked by special attractions either in their flowers, their structure, or their history. A description of all, or even a passing reference to them, would exceed the bounds of my notes, but a few of the most remarkable may be briefly alluded to. The charming *Eichornia azurea* was in first-rate condition, growing vigorously and flowering abundantly, and, like the aquatic plants generally, seemed thoroughly at home. It had increased very rapidly, and several botanic gardens where its culture had been unsuccessful obtained fresh supplies from Oxford. There also appears to be a probability of the plant becoming popular for ponds and tanks out of doors, as Mr. Robert Baxter informs me that in August last cuttings were placed in the pond there, and the plants thus obtained grew fast and flowered beautifully until November, attracting considerable attention from visitors.

Limncharis Humboldtii and *L. Plumieri*, the South American allies of our British "Flowering Rush," as the *Butomus umbellatus* is inaptly termed, were notable for their pale yellow flowers of brief duration but freely produced. They are both admirably adapted for cultivating with Nymphaeas or similar plants and are easily managed. The Water Caltrops (*Trapa natans*) was flourishing in one portion of the tank. This plant is invested with much interest, as is generally known; but, for the benefit of those unacquainted with its peculiarities, it may be stated that it is chiefly remarkable for its seed, which has a strange triangular form, suggestive of the instrument indicated in the popular name. The seeds also abound in starch, which has given rise to their use as food in some countries. For instance, they are stated to be so employed in Venice, where they are known as Jesuit's Nuts, and in other parts of Europe they are converted into flour. But as a food product the species *Trapa bispinosa* is even more remarkable, for we learn on good authority that the seeds form a large portion of the diet of several thousand persons in Kashmir during five months of the year. The ally of our native Pillwort, *Salvinia natans*, with its neat elliptical leaves closely studded with bristle-bearing warts on the upper surface, and arranged in a pinnate manner on the stem, is always attractive to the lover of vegetable curiosities. It was growing most vigorously, as well as its diminutive relative *Azolla pinnata*, and the still smaller *Riccia fluitans*, the latter of considerable interest to the microscopist. Those pretty Scrophulariaceae marsh plants *Herpestis Monnierii* and *H. reflexa*, with their pale blue flowers and thick leaves, were in good condition upon some soil at the edge of the tank; while among larger plants in pots were handsome specimens of *Thalia dealbata*, *Caladium distillatorium*, *C. esculentum*, *Cyperus pseudo-giganteus*, and *Papyrus antiquorum* that added considerably to the beauty of the house. I had nearly omitted to mention that the *Nelumbiums* were also very attractive, both *N. speciosum* and *N. luteum* being in fine condition and flowering well.

A brief notice of one other plant and I will conclude my remarks upon this house, which have already proved somewhat lengthy. It is the rarely seen *Houttuynia cordata* I wish to draw attention to, for when well grown and in flower it is elegant and striking. It is a marsh plant from Tropical Asia and Japan, and is one of the few representatives of the small natural order Saururaceae, which is allied to the Piper family. The flowers are individually of little beauty, but they are borne in a close compact spike several inches long, at the base of which is a ring of large

white bracts, constituting the chief floral beauty of the species. The leaves are, as the specific name implies, cordate in form, and their rich green colour renders the plant at all times worth growing where sufficient heat and moisture can be provided.

Of the occupants of the several other houses much could be written without exhausting the subject, but I must confine myself to a very cursory description of the most noteworthy. In a stove near the aquatic house were an extremely large specimen of the brilliant *Euphorbia splendens*, and one of the oldest plants of *Chamaerops humilis* in this country. It is said to have been in the Oxford garden for over one hundred years, and appears likely to last for a long time yet. *Xylophylla latifolia* was represented by a large plant bearing the flowers in the peculiar manner which characterises the genus—namely, on the margins of the leaves, or, more strictly, phyllodes. The house devoted to Ferns contained a good collection, including several rare species, and generally healthy. A cooler structure was occupied by Cape Pelargoniums, bulbs, and Haworthias. Of the last-named genus a number of species and varieties are grown, some being far more attractive than the majority of succulent plants, though they are comparatively little known except in a few large collections. The house specially reserved for such plants contained many specimens of great age; the two most notable being *Cereus heptagona*, one of the oldest inhabitants of the gardens, and *Cereus senilis*, 14 feet in height and about 8 inches in diameter. *Aloe socotrana* was also very fine, and several others were similarly remarkable. There remains one plant to notice that I have never seen in cultivation before, and perhaps there are few other botanic gardens where it could be seen—namely, *Conferva ægagropila*, the Vegetable Ball or Cow's Cud, a most peculiar species of a singular genus. It consists of dull green slender filaments, which grow in lakes and similar situations, but at Oxford is grown in a vessel of water placed in one of the houses. These filaments are at first loose, but gradually become aggregated, and finally form a firm spherical ball usually $2\frac{1}{2}$ to 3 inches in diameter, but it sometimes attains a greater size, as I have seen dried specimens fully 6 inches in diameter, but these also included several other substances. As a curiosity perhaps the plant is not rivalled in the whole collection.

The hardy plants, like those in the other departments, are well attended and numerous, but unfortunately at the time of my visit the weather was so wet that it precluded any satisfactory examination of the grounds. Therefore to another visit, which may possibly be made under more favourable circumstances, I must defer any notes upon that portion of the garden. I cannot, however, conclude these brief and incomplete jottings without expressing my thanks both to Mr. W. H. Baxter and his son for their courtesy during my short stay at Oxford.—L. C.

THE METEOROLOGICAL SOCIETY.

PHENOLOGICAL OBSERVATIONS FOR THE YEAR 1880.

THE usual monthly meeting of this Society was held on Wednesday the 15th inst. at the Institution of Civil Engineers, Mr. G. J. Symons, F.R.S., President, in the chair. After the election of new Fellows a paper on the above subject was read by the Rev. T. A. Preston, M.A., F.M.S., who stated—Agriculturally speaking the year may be considered as disappointing. Till June the weather was such as has rarely been experienced for farm operations. The severe cold of the winter broke up and mellowed the soil, and the dry open weather enabled farmers to clean their land from the excessive growth of weeds caused by the damp of the year before. The dry May was not favourable for the hay, which suffered severely in some places; but still a crop with far more real nourishment in it than would be obtained from a rank growth would have been secured had it not been for the terrible floods of July in the midland counties, which not only seriously injured the crop, so that it was frequently not worth the trouble of removing off the land, but also carried it entirely away in low-lying districts. The corn, again, which was looking most promising till July, suffered much during that damp period, and had it not been for the subsequent fine weather would have been ruined. But the unfavourable season of 1879 produced very serious effects on vegetation, especially on trees and shrubs, and their produce. The young wood of the trees was not ripened, and as a natural consequence the severe winter killed an enormous quantity of some kinds, and greatly injured others. *Laurustinus* was generally killed to the ground, and in some districts the destruction of other shrubs was severely felt. The evergreens in many cases lost large quantities of their leaves. Hollies especially are mentioned by several observers, and Privet hedges were sometimes quite leafless. With respect to fruit trees, Apples and Pears in some localities, but not all, were hardly able to put forth any bloom, and the crops were consequently extremely poor. Wall fruit was also a general failure, but this was partially owing to severe weather when the trees were in bloom, for in some instances the show of bloom was splendid. Gooseberries and Currants produced enormous crops, and Strawberries were very fine, but they lasted an unusually short time. Seeds generally ripened with difficulty; much

of the corn could not be ground, and a great deal was mixed up with roughly ground Indian corn, and flavoured to induce the cattle to eat it. The crop of ordinary garden seeds was also far below its usual quality, and some of the favourite garden flowers were consequently very poor. Among the special features of the year may be mentioned the great quantity of certain insects. Aphides were in astonishing numbers in the early part of the year. The Apple shoots before the leaves expanded were in almost every case covered with this green fly, and among wild plants the Guelder Rose was especially attacked by them. Wasps, again, have been in extraordinary numbers, and dreadful accounts of them have been sent to the various entomological periodicals; their numbers appear to have exceeded all previous experience. The larvæ of the Gooseberry moth and of the Gooseberry sawfly have also been extremely destructive; and finally, as an undoubted

result of the wet season of 1879, the larvæ of the crane fly have been a perfect plague in some localities, and sheep ticks in others. The scarcity of small birds has been generally noticed; some, no doubt, perished from the cold, but vast numbers had migrated. The enormous numbers of larks which hastened to the eastern counties on the outbreak of cold weather was astonishing.

PEAR VAN MONS LÉON LECLERC.

IN any reference to Pears that usually ripen in November, numerous and good as they are, this imposing variety must not be omitted. It is not only one of the most handsome of Pears, but is of excellent quality, and the tree is a good grower and bearer. It

Fig. 103.—PEAR VAN MONS LÉON LECLERC.

makes one of the finest of wall trees, and is worthy of a good position; it is also well suited for growing as an espalier, while it makes a good pyramid on the Pear stock. In sheltered places it succeeds as a standard, but to have fruit of the largest size the tree should be trained to a wall. The specimen figured was gathered from a diagonal cordon. The following is the description of the variety:—

Fruit large, sometimes very large, 4 or 5 inches long, and 2½ to 3 inches wide; oblong-pyramidal, undulating and uneven in its outline. Skin green at first, but changing to dull yellow, covered with dots and tracings of russet. Eye open, with spreading segments, set in a shallow basin. Stalk 1 to 1½ inch long, curved, and inserted in a shallow cavity. Flesh yellowish white, buttery, and melting, very juicy, rich, and with a delicious sprightly vinous flavour.

This Pear was raised by M. Léon Leclerc of Laval, formerly Deputy for the department of Maine, and named in honour of Dr. Van Mons. The tree first fruited in 1828.

TYDÆAS.

THESE plants are amongst the most beautiful that can adorn the stove, no matter at what season of the year they are produced. Even in summer they are delightful, and quite distinct from Achimenes. During autumn and winter they are invaluable, and will flower profusely throughout the dreariest and darkest months of the year. It is surprising that Tydæas are not grown more largely in the majority of gardens, when the easiness with which they are cultivated is taken into consideration compared with that of many plants not nearly so beautiful. They continue

much longer in bloom than many flowering plants, and when well grown produce their beautifully spotted flowers in succession over a great space of time.

In commencing the cultivation of these plants it is wise to obtain them while in a resting state, and by judicious care in starting some at intervals of a month a supply can be obtained through the whole year. It is difficult when first obtaining the small tubers to adapt them to winter growth. This difficulty can soon be overcome by keeping those required for late flowering at rest as long as possible, and in a season or two the whole stock can be started at any time. It is wise to keep the different batches separate, either by labelling or otherwise, or some of those required first may be left, while those for late work may by mistake be potted earlier than intended. In starting them into growth the small tubers can be placed either in the pots the plants are intended to bloom in, or they may be placed in small pots, afterwards transferring them into others 5 or 6 inches in diameter, which are large enough for single plants. The plants do well on either system, but the latter is preferable, as the soil is not so liable to become sour before the pots are filled with roots. If the pots can be plunged in bottom heat so much the better, and the quicker will the tubers commence growth, although bottom heat can easily be dispensed with, and when growth is a little advanced they do as well without it. A temperature of 60° to 65°, regulated according to the outside temperature, is ample if increased as the season advances. During summer slight shade is beneficial on hot bright days, but excessive shading will cause them to draw up weakly and flower unsatisfactorily. As before stated, a few started every month will maintain an unbroken supply. Tubers potted at the commencement of the new year will produce flowering plants by the end of May and through June, and plants started at the beginning of May will bloom by the end of September and through the following month. In autumn and winter they are most useful, and to have a good supply batches should be potted from May until August; and as the growth is not so rapid during the declining days of the year, those started in August will maintain a supply until late in the spring. When plants have to grow through the winter it is necessary they have a light position close to the glass, and care must be taken not to cause a check to their growth.

The pots when used should be clean and well drained, a layer of moss being placed over the drainage, then nearly filled with the compost, placing a little sand in the centre, in which to embed the tubers, care being taken to have their growing ends near the centre, and covered with the compost. This should consist of good fibry loam, a liberal admixture of leaf soil, a seventh of manure, and sufficient coarse sand to keep the whole porous. Peat may be used as a substitute for the leaf soil if more convenient, but the soil must be light and rich. A number can be placed together in the same pot if large specimens are required, but for all ordinary decorative purposes 6-inch pots are large enough. Tydæas, if properly attended to when resting, make strong growth from very small tubers. When placed in the small pots and the roots reach the sides they should be transferred into the larger size, only removing the drainage, and injuring the roots as little as possible in carrying out the operation. While in active growth the plants require liberal applications of water at the roots, except immediately after they are repotted, when water should be applied with care and judgment until the roots have permeated the new soil. When the pots are full of roots liquid manure may be supplied with advantage. Syringing the foliage is not needed, and indeed the leaves when wet are often injured by exposure to the sun.

The resting period is by no means the least important, and success to a large extent depends upon the treatment then followed. Tuberous-rooted plants of this nature are often neglected by allowing them to remain in cold potting sheds, or by storing them away under the stages. Neglect in this respect brings Tydæas into an unsatisfactory state, and instead of increasing in numbers and gaining strength year by year they become weaker, and in a few seasons are almost useless. If, however, after flowering they are liberally supplied with liquid manure, it will assist considerably in increasing the size of the tubers, which must be plump and matured before resting. The plants must have attention until the foliage commences dying, when they can be kept somewhat drier and allowed a similar temperature to that in which they were growing. When finally at rest they can be stored away in any cool place where a temperature ranging between 35° and 40° can be maintained. Tydæas will not endure being kept quite so dry while resting as Achimenes. It must be borne in mind their tubers differ considerably from those of Achimenes, Tydæas being more like underground stems.

The following are twenty excellent varieties well worthy of

cultivation:—*T. alba nigra*, *Alexandre*, *Amarante et cannelle*, *Corneville*, *Etna*, *gigantea*, *Hercule*, *Itaculum*, *Junon*, *Leandre*, *Madame Heine*, *Minerve*, *Robert le Diable*, *Pluton*, *Batafago*, *Sapé*, *Themistocle*, *Tricolore*, *Wonder*, *Xenophon*.—WM. BARDNEY.

RARELY can a horticulturist visit our great metropolitan emporium of fruit, vegetables, flowers, and plants—COVENT GARDEN MARKET, without seeing much to interest him, but one of the most stirring times is the present. The preparations for the Christmas demands is shown on all sides. Such largely consumed commodities as Oranges, Nuts of many kinds, the indispensable Mistletoe, and the seasonable Holly form the chief features in the display, but unfortunately the last-named is sadly deficient in the number of its berries. Of cut flowers there is abundance, including such generally appreciated kinds as Roses, Violets, Lilies of the Valley, Camellias, Eucharises, Hellebores, Bouvardias, Primulas, Hyacinths, Chrysanthemums, Zonal Pelargoniums, Euphorbia jacquiniæflora, and a few Orchids, principally *Calanthes* and *Odontoglossums*—a goodly list. The seed vessels of *Iris foetidissima* with their brilliant scarlet seeds are strongly represented, and the "Everlasting Flowers" of varied colours also add to the attractions. Plants, fruit, and vegetables are all displayed in similar profusion and excellence.

— AMONG the "Everlasting Flowers" noted above, the flower heads of *ASTELMA EXIMIUM*, THE STRAWBERRY EVERLASTING, are particularly attractive. The bracts are of a rich rosy tint, and incurved so as to form close heads, bearing some resemblance to Strawberries. The plant is a native of the Cape, and has long been known in this country, but is comparatively rarely seen. Messrs. Smith & Larke of Kensington exhibited specimens of the flower-heads at the Royal Horticultural Society's Meeting on the 14th inst.

— "A VISITOR" sends us the following note on *BEGONIA SEMPERFLORENS GRANDIFLORA*:—"On the two occasions that Mr. W. Iggulden, Orsett Hall Gardens, Romford, has exhibited his variety of the well-known *Begonia semperflorens* I have been attracted by its floriferousness, the large size of the blooms, and the good habit of the plant. At the last meeting of the Royal Horticultural Society these characters were particularly notable, and I have seen plants honoured with certificates that were in my opinion less distinct and useful for decorative purposes. It unquestionably appears to well merit the name *grandiflora*."

— FROM a recent communication we learn that THE WINTER GARDEN IN THE PARK AT SUNDERLAND—which, by the way, is the only structure of its kind in the north of England—has been unusually gay this autumn with Chrysanthemums, including fine specimens of *Mulberry*, *Calliope*, *Model of Perfection*, *Novelty*, *Ariadne*, *Queen of England*, *Empress of India*, &c., besides a number of excellent plants of zonal Pelargoniums all in full bloom, and dispersed amongst the foliage plants. Palms planted out have a most pleasing effect, the ground being carpeted with *Selaginella*; but the chief feature in the winter garden at present is, amongst the many fine climbers that adorn the walls and pillars, *Eupatorium odoratum*, associated with *Tropæolum Lobbianum*; the effect of the scarlet *Tropæolum* and the cream-coloured *Eupatorium* in combination is very beautiful. All who wish to have the flowers of this *Eupatorium* in the autumn in quantities should plant it out in an intermediate house.

— A CORRESPONDENT writing upon the WEATHER IN THE NORTH OF ENGLAND observes—"It is not often in the north that such fine weather has been experienced as we have had this autumn. Outside operations of all kinds have progressed most favourably. With one slight fall of snow in November, and another on December the 16th, which scarcely lasted twenty-four hours, the weather had been most favourable. Since then there have been severe frosts, and temperatures of 7°, 8°, and 10° below zero having been registered, accompanied by dry cutting north-east winds."

— ONE of the pretty winter-flowering Orchids exhibited by Messrs. J. Veitch & Sons at the last meeting of the Royal Horticultural Society was *DENDROBIUM ENDOCHARIS*, a hybrid obtained by Mr. Seden a few years since from crossing *D. japonicum* with *D. heterocarpum*. It partakes of the characters of both parents, but possesses several clearly defined and distinctive marks. The flowers are produced in pairs from the nodes of the growths, and are white with a purplish blotch in the labellum, the delicious fragrance exhaled being suggestive of Violets. As the nodes on the numerous stems are closely placed, a specimen of moderate size has a pleasing effect when in flower.

— AT J. Brand, Esq.'s residence, Bedford Hill House, Balham, the old *CAMELLIAS* PLANTED OUT in a cool house, and trained to the back wall, are this season in remarkably healthy condition; the foliage a most intense glossy green; the flower buds of great size, and so abundant as to give promise of a beautiful display a week or two hence. The *Calceolarias*, which annually form such attractive groups at some of the summer exhibitions, are a sufficient proof of Mr. Rapley's skill as a plant-grower, but with *Camellias* and *Eucharises* he seems to be equally successful. The enormous specimens of the latter plants, about a yard in diameter and growing in tubs, have been magnificent, the five largest having borne about 150 scapes of handsome flowers. The most noteworthy plant in the stove at the present time is the useful and brilliant *Euphorbia jacquiniæflora*, which is represented by numerous small specimens.

— "A GARDENER" writes:—"There is now a grand display of *POINSETTIAS* AND *CALANTHES* AT HAWKSTONE, the seat of Lord Hill. They are arranged alternately, and the effect is magnificent. The *Poinsettias* vary in height from 12 to 16 inches, having very large bracts of the brightest scarlet. The *Calanthes* are principally forms of *C. Veitchii*. One or two pseudo-bulbs are grown in each pot, are strong, and the spikes of flowers very beautiful. Mr. Pratt is very successful in the cultivation of these plants."

— ON Saturday evening the 18th inst. Mr. Glover, Lee Hall, read before the members of the LIVERPOOL HORTICULTURAL ASSOCIATION an excellent paper on the cultivation of the *Odontoglossum*, followed by a very interesting and highly instructive paper from W. B. Halhead, Esq., the Honorary Treasurer of the Association, "On the Germination of Seeds." Mr. Halhead takes great interest in this portion of the Association's work, and has induced several gentlemen to promise to read papers at future meetings. The meeting terminated with the usual vote of thanks to Mr. Richardson, the Chairman.

— THE dinner given to their *employés* by MESSRS. WAITE, NASH, HUGGINS & Co. to celebrate the amalgamation of the two houses, was held on Saturday evening last at the Imperial Hotel, Southwark Street, Mr. J. C. Chapman presiding, with Mr. R. W. Jack as Vice-Chairman. The evening was passed very pleasantly.

— MR. ALEX. CHRISTIE, Warnford Park, Bishops Waltham, succeeds Mr. D. Judd as gardener to the Earl of Warwick, The Castle, Warwick; and Mr. FREDERICK THOMSON, Woodville, Reddish, near Stockport, succeeds Mr. Simpson as gardener to W. Baring, Esq., Norman Court, Dean, Salisbury.

— LAST week the Baroness Burdett-Coutts opened a public Exhibition of natural and artificial flowers and plants, in aid of the LONDON FLOWER GIRLS' BRIGADE. The object is to elevate young girls who vend flowers in the streets. The girls, about fifty or sixty in number, are clothed in a neat dress, not strictly a uniform, but of similar materials and makes, and they wear an ivory badge on a blue ribbon. They are supplied with flowers, which are bought in Covent Garden Market, and are never allowed to be under any but the Brigade room roof, and on the sale of these flowers they receive a small commission, besides regular weekly wages. They are stationed in places where they can sell their flowers, either bouquets or for the button-hole, secure from insult or molestation; and they are sent with supplies to regular customers in various parts of London. In the winter they are trained to manufacture artificial flowers, a work for which they show great aptitude, by reason of their early familiarity with natural flowers, and their unconscious observation of their growth and peculiarities of foliage and bloom. Bouquets, also artificial, under glass shades, were in abundance on the stalls. Nosegays and flowers for the buttonhole presented an attractive spectacle. Some twenty or thirty of the "Brigade" girls were at work, in the manufacture of these artificial flowers, at a table in the centre of the hall. The principle of division of labour obtained among them. Each made a certain portion of a flower, and others put together the component parts.

MELON CULTURE.

NOTWITHSTANDING "A KITCHEN GARDENER'S" criticisms (page 556) upon my few remarks (page 509) I am still sceptical, and in fact believe artificial assistance to Melons, either by fermenting materials or hot water, at some stages of their growth to be absolutely necessary, and I very much question the soundness of his advice to amateurs in representing artificial heat as unnecessary, unless raising and growing the plants strongly is not part of their culture. Melon-growing is certainly more expeditious with fermenting materials than without, although failures occasionally occur by an excess of heat and the very simple details of preparation of the materials being carelessly and slovenly managed. On the other hand, as good fruit may be and are grown in a two-light box as in the most elaborate Melon house. What say our large growers? If "A KITCHEN GARDENER'S" criticisms be rightly understood very many gardeners go to very much unnecessary trouble and expense, as the only thing to do is to sow a few seeds in the garden and bring a two or three-light frame and place over them, Nature doing the rest. If agreeable to "A KITCHEN GARDENER," and he will advise me to this effect, I will endeavour to make a pilgrimage to see so great a novelty whenever ready, as I am not too old yet nor too conceited to learn how to grow Melons without artificial heat.—W. CRUMP, *Blenheim*.

GLEICHENIA DICARPA VAR. LONGIPINNATA.

GLEICHENIAS now hold a foremost place both in ferneries and at horticultural exhibitions, and very deservedly, for when well grown they are extremely graceful owing to the distinct habit, the fine divisions of the fronds, and their drooping tendency. The species *G. rupestris*, *G. Mendelli*, *G. circinata*, *G. flabellata*, *G. dichotoma*, *G. speluncae*, and *G. dicarpa* are all well known and appreciated, together with several varieties. One of the latest introductions and one of the most handsome is the form of the last-named species, appropriately termed *longipinnata*, which Mr. B. S. Williams of Upper Holloway obtained from Australia a year or two since. It has already attracted much attention from Fern-growers and exhibitors, and the latter are likely to find it a great acquisition, as a large specimen would be most imposing in a collection. I have not seen one of extraordinary size at present, but several excellent "half specimens" have recently come under my notice. The best of these I observed in the collection of an experienced grower and exhibitor, who speaks highly of the variety, which he thinks will soon be considered as one of the most effective for the purpose named. Small plants are, however, admirable for warm greenhouse decoration, and are scarcely excelled in the genus.

G. dicarpa longipinnata resembles the species of which it is considered a variety, but is distinguished chiefly by the greater

length of the pinnæ, as the name implies. Each of these are about 5 or 6 inches long, thus giving a breadth of 10 or 12 inches to the two or four divisions of the frond, which is also longer than in the type. In colour the young fronds are particularly attractive, for the rich deep green is tinted with a metallic blue that is very striking, and the lower surface has a fine glaucous hue. Other valuable characters are freedom and quickness of growth, in which respects it surpasses most of the species in general cultivation—amply sufficient to recommend it.—R.

REVIEW.

The Herefordshire Pomona. Edited for the Woolhope Club by ROBERT HOGG, LL.D., F.L.S., &c. Part III.

THIS magnificent work goes on as it began; it has not belied its first promise, but if anything Part III. is beyond its predecessors. It follows the same lines. Just as in Part I. we had Dr. Bull's paper on the "Early History of the Apple and Pear," and in Part II. the same writer's article on "Modern Apple Lore," so here in Part III. we have as introductory papers "The Crab, its Characteristics and Associations," by Mr. Edwin Lees, and Mr. Bulmer's treatise on "The Orchard and its Products," the latter an exceedingly practical paper, treating of the orchard, soil, surface, drainage, aspect, climate, and site, manuring and planting; then orchard trees; seedlings, budding and grafting; varieties, old and new; pruning, and those enemies of the orchard tree Mistletoe, blight, and red spider. Forty coloured figures of Apples and Pears follow, with sections of the same and descriptions. So much in regard to a general view of Part III. recently issued from the press.

Mr. Lees, in his history of the Crab and its associations, carries us in thought away from winter and its dreariness to May and its blossoms, when

"The jay's red breast
Peeps over her nest
In the midst of the Crab blossoms blushing,"

and makes one see the Crab's delicately blended pink-and-white blooms, prettier far than the Apple. He tells us that the Crab existed in Europe and Asia *ab origine*, that it is mentioned in the Scriptures, that in the earliest days of England the roasted Crabs hissed in the bowl; still, the Crab of itself is a poor fruit, only eaten with relish by each generation of rustic schoolboys, who will eat anything that looks like fruit. Harsh is the taste of the Crab, rugged its growth, and "crabbed" is a word taken from it and used to denote a very unpleasant type of man, for who of us wishes to have as a companion "a crabbed fellow?" A Crab stiek, too, was a peculiarly harsh and unpleasant weapon used only by these crabbed fellows. This Crabstick discipline no doubt originated in savage times, and was perpetuated by only savage natures. Of such was the man in Southey's ballad, where we learn that

"Richard Penlake a scolding would take
Till Patience availed no longer;
Then Richard Penlake his Crabstick would take,
And show that he was the stronger."

Mr. Lees quotes, of course, from Shakspeare (we can quote Shakspeare on any subject!), from Milton, Cowley, Pope, and others to illustrate his subject. He tells us that even now (and we are surprised at it) Crab vinegar is still made in some secluded rural districts, and gives us an anecdote to prove its truth—that a farmer left behind him at his death a hogshead of this very sour vinegar—that his executor had it put in a barn, imagining that no such sour liquid would be furtively tapped. He was, however, mistaken, for the labourers drank it, and so at the sale the cask was there but no liquid. Verily Worcestershire labourers would drink anything. Even our Wiltshire chawbacons object to sour beer, calling it "rot-gut," but Worcestershire internals must be proof against all injury, and Worcestershire throats greedy in the very extreme.

Mr. Lees carries us on merrily as to the uses of the Crab—how when roasted they were thrown hissing hot into the spiced ale; how that west country damsels (Somerset girls, we suppose) gather Crabs, and putting them into a loft form them into the initials of their supposed suitors' names, and those remaining most perfect on Old Michaelmas day were those of their truest lover. Nor is Shakspeare's Crab tree near Bidford forgotten, though, like the deer-stealing tale, we do not believe a word of it.

Crabbing the Parson must have been unpleasant work, at least for the poor parson, who on Dec. 13th, the feast of St. Kenelm, had to run to church amid a shower of Crabs thrown by village boys. But the days of Crab eating, and Crab use, and Crab

merriment are over. Yet as the remote ancestor of all the excellent cultivated varieties of the Apple, the Crab deserves to be remembered. May we enjoy its blossom and have that only in our thoughts, not crabbed relations or crabbed acquaintances; friends of crabbed people we should certainly not make.

Next follows "The Orchard and its Products"—cider and perry. This useful paper is to be continued in the next part of the *Pomona*. One of the mottoes or quotations at head of the chapter is this suitable one from Lord Bacon, "We had also a drink, wholesome as good wine of the Grape, a kind of cider made of the fruit of that country." It always is a surprise that with cider so easy of production that light claret, so utterly inferior as a drink, should be increasingly consumed, and I fear cider to the bulk of the population of this country is almost unknown. We cannot grow the Grape profitably, but we can grow the Apple. Somersetshire labourers work ably and gladly on cider; I doubt whether in this climate they could on that dark-coloured vinegar known as Gladstone claret. We need not import Apples from America if we were only energetic, and we equally need not so largely import light claret from France, a drink that, save on a hot summer day, is unsuited to us; and then on a hot summer day what so delicious as cider?

Mr. Bulmer in this chapter traces back the cider orchards in Normandy to the eleventh century, then their increase in the thirteenth and sixteenth centuries; but that it was not till the seventeenth century had been well advanced that cider orchards were much planted here in England. Continental wars caused wine to cease to be imported, and we depended upon our home-made drinks. Poets and writers praised cider and perry. Squires and growers vied in its production, and success of course was the result. The labourers had a harmless and wholesome drink, so unlike the muddy muddling poisoned beer now obtained at the low public house. The prosperity of orchards was, however, not for long. Land was wanted for corn-growing and cattle-feeding, and orchards were neglected—just, in fact, an opposite state of things to that in this day; so cider and perry went down and bad ports and sherries came up. On the continent it was the same—the same, too, half a century since in America, but is not so there now; for American farmers are beginning to recognise the fact that no farm is complete without a well-selected and well-cultivated orchard. It should be so in England, for wisely says Mr. Bulmer, "If free trade in corn and the introduction of live and dead meat restrict the profits of the farmers, happy are they who, as in the fruit districts of England, have their orchards to help them." Mr. Bulmer further states that "the present condition of the English orchards is far from satisfactory, and they show sadly the result of long-continued neglect."

After this essay, practical remarks upon the soil suited for an orchard follow, headed by this general observation—"The Apple tree certainly prefers a sandstone wherever it is found, as the Pear rejoices in calcareous soil." Still Apples and Pears often do well on neither soil. Magnificent Apples grow on the gravelly islands which lie among the Fens, and Pears do the same, though, no doubt, as old T. Andrew Knight observes, "Every variety of Apple is more or less affected by the nature of the soil on which it grows." In regard to cider fruit the soil is more important. The whole of Mr. Bulmer's paper is well worth reading by all intending to plant an orchard, with a view particularly to the production of cider and perry. It is an able paper, interestingly, and therefore well written, for whatever is dull in style is a trouble to read and hard to remember.

Next follow what all eyes appreciate—viz., the pictures. These are quite equal to those in the former parts. Plate 15, three baking Pears—Catillac, Uvedale's St. Germain, and Bellissime d'Hiver, all admirably done, the last being perhaps the best. Following every plate are sections and descriptions of the varieties pictured, all extremely valuable. Plate 16, Golden Harvey and Cox's Orange Pippin, two of each kind at different stages of ripeness, with a sprig of blossom of each. Plate 17 contains portraits of five excellent cooking Apples, all large and fit for exhibition—Waltham Abbey Seedling, Bedfordshire Foundling, Ecklinville Seedling, Hanwell Souring, and White Spanish Reinette. Plate 18, groups of perry-producing Pears, small and brown, with a glowing cheek for the most part. Plate 19, brightly coloured summer-eating Apples—the excellent Margaret, the pretty Summer Strawberry, and the matchless Irish Peach. In plate 20 are two thorough exhibition Apples—Yorkshire Beauty and Lodington or Stone's Apple. No Americans are beyond these in appearance. The latter, though bearing the name of a Kentish village, was originally from a nursery near Bath. Plate 21, two striking groups of Apples; first Russets, with the apt quotation under, "There's a dish of Leathercoats for you," the words bringing to one's mind Justice Shallow's seat in Gloucestershire,

that not by any means clever master, and his equally foolish men. I think the dish of Leathercoats might have been appropriately represented on a dish of the period. The lower picture "Nonpareils, an it please you." These are among the very best illustrations in this part, for they seem as if they would roll off the paper into your lap. Plate 22, three Pears—Beurré Superfin, Triomphe de Jodoigne, and Beurré Duhaume. In Plate 23 we return to cooking Apples—Golden Noble, Dr. Harvey, and that best of sorts for an espalier particularly, Warner's King. The 24th and last plate gives us three capital Pears—General Todtleben, Soldat Laboureur, which by the way is one of the few late Pears which always does well as a pyramid; and lastly Beurré Bachelier.

One lingers over this work from its truthfulness and beauty. One writer says of "portrait painting" "that it should be truth lovingly told;" so of the fruits here pictured. They are not gaudy fancies, and not bare reproductions; but they are Pears and Apples pictured truly yet favourably—just what they should be. Dr. Hogg's descriptions are, as always, very accurate, and the number of synonyms a great help to the learner.—WILTSHIRE RECTOR.

JASMINUM GRACILLIMUM.

At the last meeting of the Royal Horticultural Society the plant that attracted the most general attention was the distinct, fragrant, and floriferous

Fig. 104.—JASMINUM GRACILLIMUM.

can only be displaced by shaking them with considerable force. It is a graceful and attractive plant, and will in due time find its way into all gardens where choice stove plants are grown, and pure, chaste, and highly perfumed flowers are cherished. As was remarked on page 554, the honour of having introduced this acquisition to our plant stoves is due to Mr. F. W. Burbidge, who found it during his travels in Borneo.

GARDEN REFUSE AND ITS USES.

YOUR correspondent Mr. Iggulden, at page 503, has commented upon a most important subject, and yet one in many establishments greatly neglected, and it is much to be hoped his able

Jasmine, a spray of which is represented on fig. 104. As a stove plant this will prove an introduction of sterling worth. It is not necessary to train the growths to a trellis, but by judiciously stopping them during growth, and a little tying, free bushy specimens may be obtained, or stands with semi-loose informal heads covered with flowers. Some of the large terminal clusters have comprised as many as fifty flowers and buds with axillary flowering growths of considerable size. The flowers are pure white, of the form represented, and the largest are $1\frac{1}{2}$ inch in diameter. For affording choice cut flowers this Jasmine will be of great value, as, unlike most others of the genus, they do not so soon fall when severed from the plant, but, on the contrary, they

remarks may remedy the evil in places where little excuse can be made. His arrangements for disposing of the refuse of the pleasure grounds are admirable and much to be recommended where practicable, but I have found much inconvenience and annoyance from the kitchen garden rubbish being employed, as it is with considerable difficulty that the vitality of the seeds are destroyed. I have very fresh recollection when living in the west of having used some garden refuse that had been heaped and thoroughly decomposed upon beds in the flower garden, in which a somewhat intricate geometrical plan was afterwards carried out. The result was that we were constantly employed in keeping down weeds which came up in dense numbers.

Another instance occurred this season when taking the gardens

now under my charge. The accumulation of some years had formed a large heap, which was ultimately thrown up into two large heaps, intended for grass land. The lower portion was so much decayed that I thought no seeds could possibly trouble us, and it was accordingly used in some beds in an old-fashioned flower garden. The weeds came up worse than before and caused us much trouble, so the remainder will be taken to the farm. The refuse of this season, in the form of burnt ashes, is now in a dry corner in the shed. In spite of the wet summer everything, except present prunings, have been burnt, and the ashes carefully sifted and stored. We manage by judiciously banking up the fire and attending regularly to keep it in many days together; the result being a heap of ashes, the value of which is only known by those who carefully store it one season and liberally use it the next.—J. W. SILVER.

HARDY FRUIT GARDEN.

In open weather planting fruit trees may be proceeded with, and as soon as they are planted the ground should be well mulched with littery manure to resist frost and keep the soil in a moist equable condition, which is of great importance to the success of newly transplanted trees. Where the condition of fruit trees on walls or in the open is unsatisfactory the roots must be carefully examined when it will frequently be found that remedial measures may be employed with good results. Over-luxuriant fruit trees, whether trained to walls, or as espaliers, pyramids or standards, can generally be rendered fruitful by judicious root-pruning. This should, however, be carefully performed, cutting back the strong bare roots, and preserving as many of the small roots and fibres as possible, laying them in fresh soil near the surface. It is impossible to give particular rules for root-pruning, as that will need to be varied according to the vigour of the trees and the condition of the roots.

Trees of moderate age that are very vigorous and have not previously been root-pruned, will probably have the roots considerably elongated, thick, and with few ramifications near the stem. To cut those all away at once at a distance of 3 to 6 feet from the base of the tree would give a check that the tree may not recover from at all, or take a considerable time to do so satisfactorily. In cases of this kind only a portion of the strongest roots should be cut in a season, say the thickest of the roots at a distance of from 3 to 6 feet from the stem, according to the size of the tree; cutting them off clean and transversely, and removing from the soil as far as possible the portions severed. The cut-back roots will in two seasons have formed roots freely near the stem, when those not subjected to the process in the first instance may undergo similar treatment. In root-pruning generally, the roots should be laid bare to a distance of 6 feet from the stem, cutting back any that are thick and fibreless, and as far as possible to an angle, as in the case of removing superfluous branches from the head. If they are deep they should be raised and laid out carefully near the surface. In cases of weakness in the trees let the surface of the soil be carefully removed so as to expose a considerable portion of the roots, and after cutting out any decayed parts and taking out the old soil, work some good turfy loam among them, and cover them about 3 or 4 inches deep; render the soil moderately firm. Operations of this kind should be done in dry weather, mulching at once with littery manure.

In the renovation of fruit trees, where the soil is light and shallow an addition of fresh turfy loam with clay or marl will be favourable, and should be supplemented by liberal surface dressings of cool manure. Where the soil is rich restriction of the roots by biennially cutting them at about 4 to 6 feet distance from the stem all around will check the tendency to undue vigour, and maintain the trees in a fruitful condition. Where trees make sappy and late growths, the soil, in addition to being rich, is probably wet, which can only be rectified by a thorough system of drainage. In cases

where trees of considerable age have become unproductive, the variety of inferior quality, or unsuitable to the situation, they may now be headed down, particularly standard trees, and grafted in spring with more suitable varieties. Locality and soil have much to do with the bearing and quality of Apples and Pears; hence in improving old trees or in forming plantations of fruit trees it is always advisable to employ largely the varieties that have been proved to succeed, not, however, to the exclusion of new varieties. Bullfinches are already becoming too attentive to the Gooseberry quarter. Sprinkling the bushes whilst wet with quicklime and soot will render the buds distasteful to the birds, and a solution of fir tree oil insecticide or nicotine soap syringed over the bushes or applied through a rose watering pot will protect them for a long time. The gun, however, is the only certain remedy except trapping.

PLANT HOUSES.

Conservatory.—Chrysanthemums will soon be over and their place taken by Camellias, which with other plants from the temperate house, in addition to those brought forward in heat, will make an effective display. To secure the free expansion of Camellia flowers a temperature of 45° to 50° is necessary in the day with a fall of about 5° at night, which is equally suitable for plants generally in flower in the conservatory at this time of year. In severe weather, necessitating abundant fire heat, care must be taken that the atmosphere is not allowed to become too dry, or the buds of Camellias will be likely to fall, especially of late varieties. The supply of water to the roots must be liberal. Fragrant flowers are never more appreciated than at Christmas, and especially is it necessary to provide a succession of such plants where the conservatory is attached to the mansion. Heliotropes that have been prepared for winter flowering should have a light position or their flowers will not open freely, and if in small pots liquid manure will be beneficial. Richardias may be introduced as their spathes open. A sufficient supply of these plants should be at command to keep up a succession until spring, their distinct foliage and stately spathes contrasting well with others. A few well-grown plants of Violets placed about the house will afford an agreeable and acceptable odour.

Pelargoniums.—Show, Spotted, and Fancy Pelargoniums are indispensable for conservatory decoration. For this purpose it is not advisable to grow specimens such as are seen at exhibitions, and at the same time do not have straggling meagre examples, but follow a middle course by growing them of a medium size and with only as much tying as will keep them shapely. Plants desired to flower in May should now have the requisite number of sticks placed to them, bringing out the shoots to their places so as to admit air and light to the centre. Young vigorous-growing plants may have the points pinched out; older shoots that do not grow so fast will, especially for early flowering, be better without stopping. Late-flowered plants will now require shifting into their full-sized pots, ramming the soil quite firmly, as when lightly potted they do not flower satisfactorily. Afford no more water than is needed to keep the soil moist, inclining to the dry rather than a wet condition. A light airy position near the glass should be afforded; and a temperature of 40° at night, or a little less, and about 5° more by day is suitable, admitting air freely at every favourable opportunity.

Roses in Pots.—Any intended addition to the number of plants grown should at once be potted, giving plenty of drainage, and employing good turfy loam with about a fifth of well-decayed manure and a sixth of sharp sand. Pot firmly, pruning at once, and place them in a cold pit where frost can be excluded, allowing them to come into flower without being excited in heat the first season. The ordinary stock should be kept cool, but where they will be safe from frost, completing any surface dressing or shifting into larger pots without delay, in the latter case only removing the old drainage and any loose soil.

Herbaceous Calceolarias.—The earliest plants will require transferring from their small pots before they become rootbound to 6 or 7-inch pots. If this be delayed they become stunted and will not grow freely afterwards. No plants repay for attention better than these, keeping them steadily advancing in growth and free from aphides. Rich thoroughly reduced turfy loam, a fourth of decayed

manure and leaf soil, with a little sand, form a suitable compost, potting rather firmly. A cool moist situation is suitable, where they can have a position near the glass, plenty of air when the weather is favourable, and sufficient heat only to exclude frost.

Pelargoniums of the Zonal and Nosegay varieties intended for spring flowering should have a night temperature of 40° to 45°, and that or a little more in the daytime. Be careful in the application of water for some time yet. Potting should be attended to where it is required, not giving too much root space, potting firmly and employing turfy loam. Stop the shoots when necessary to secure compact habit, and tie the growths well out, keeping the plants near to the glass, and the house well ventilated. Remove the flowers of plants intended for spring or early summer flowering.

NOTES ON VILLA AND SUBURBAN GARDENING.

KITCHEN GARDEN.

Forcing Rhubarb and Seakale.—Most gardens, however small, contain a few strong clumps of both these, and especially the former, some of which may be forced. Although such varieties of Rhubarb as Prince Albert and Johnson's St. Martin, are the best for forcing, any of the later varieties will well repay the trouble taken. Even the Giant Victoria, though it does not start readily, can eventually be induced to form a great number of stalks, which are of very superior flavour. Roots of any variety of Rhubarb and Seakale may be lifted and packed in rather closely under the staging of a forcing house and near to the hot-water pipes, or they may be potted or placed in boxes in a warm house. Any ordinary soil may be employed, and this should not be allowed to become dust dry. Two or three large clumps of Rhubarb are sometimes carefully lifted, packed in soil in large hampers or boxes, and placed in a warm cellar, the result being early and good produce. Seakale may be started in a garden frame on a gentle hotbed, but great care must be taken not to use rank fermenting material, or the roots will be injured and the produce be spindly. The Seakale will require to be grown in the dark, but this is immaterial in the case of the Rhubarb. In either instance the best results are obtained from those roots forced where they were grown. All that is required for this work are a few pots for the Seakale and deep boxes or tubs for the Rhubarb (ordinary flour or cement tubs with their bottoms converted into lids are very suitable), and a quantity of leaves and manure which have previously been laid in a heap for a few days. Commence operations by lightly forking up the soil round the crowns, place over these the covers with their lids on, and then bank round the fermenting material so as to bury the covers. Avoid making a great heap, preferring rather to cover a few roots at intervals of a fortnight. If leaves only are used hurdles will be necessary to keep them together. A trial stick should be thrust into the bed and frequently examined, and, should the point be found uncomfortably hot to the hand, the heap must at once be opened for a few days.

Forcing Asparagus.—A bottom heat of about 75° is very suitable for all forced vegetables. A still milder hotbed is suitable for forcing Asparagus, and where it is in contemplation to break up an old bed the roots should be utilised for forcing and then thrown away. The growth from these old plants is produced very freely, but is usually much inferior to that obtained from younger plants. Of course no one would think of breaking up good beds unless there are others to succeed them. When the hotbed is found to be in a suitable condition a layer of rather moist good soil is spread over the surface, on this the carefully lifted roots are closely laid and covered with more soil, working this well in among the roots. The soil being in a moist state and the heat also moist no water will be required at first, but a thorough supply of warm water should be given on the appearance of dryness. If the heat be mild cover the frame closely with mats or litter till the growth is pushing through the soil, when as much light as possible must be admitted, as most people prefer green to blanched Asparagus. The frames should be covered during the nights, and should the bottom heat decline below 70° a lining of fresh heating material should be given, as the growth is liable to be hard if grown in a low temperature.

Asparagus, Rhubarb, and Seakale may all be forwarded considerably where growing if sufficiently protected with rough litter. The last-

named may be either covered with the usual pots, or good-sized ordinary flower pots, or again with ashes to a good depth, then earthing prior to covering with litter.

Manuring and Digging.—It is a moot point with many as to when to manure and dig ground, and the opinions given on the subject are very bewildering to amateurs. Much depends upon the nature of the soil with regard to digging, but in most instances the manure would be best applied in the spring rather than its principal soluble manurial properties should be washed away by the repeated heavy rains. Far better shake it up into a large heap with sloping sides, a good layer of soil underneath, and more of it well beaten over the outside of the heaps, thereby enclosing the ammonia and much increasing the bulk of the manure. The manure may be wheeled into the garden during frosty weather, and be there placed in heaps and covered with earth till required.

It is advisable to roughly turn up stiff clayey soil to submit it to the pulverising influence of the frosts and winds, re-digging some time after a severe frost, working in the manure to be given. Sandy soils if dug in the autumn lose by repeated soakings much more than they gain by exposure, and both these and those that are somewhat rich, but which generally work well, had better be left unmanured and undug till near such times as they are to be cropped. Trenching being a slow operation, for which there is seldom time in the spring, should be performed on all favourable occasions. Here again manure is often worked in either too early or too deeply, and both practices should be guarded against. The manure wheeled on should be autumn-trenched during frosty weather, and be turned in afterwards.

TRADE CATALOGUES RECEIVED.

James Veitch & Sons, King's Road, Chelsea.—*Catalogue of Vegetable and Flower Seeds (Illustrated), and Lists of Gladioli and Hardy Plants.* Sutton & Sons, Reading.—*The Amateurs' Guide and Seed Catalogue for 1881. Highly illustrated.*

James Carter & Co., High Holborn, London.—*Vade-Mecum and Catalogue of Flower and Vegetable Seeds. Highly illustrated.*

B. S. Williams, Upper Holloway, London, N.—*Catalogue of Flower and Vegetable Seeds.*

Harrison & Sons, Leicester.—*Wholesale Catalogue of Vegetable Seeds.* Martin Grashoff, Quedlinburg, and Westerhausen, Germany.—*Wholesale Trade Catalogue of Flower and Vegetable Seeds.*

Friedrich Spittel, Arnstadt, near Erfurt, Germany.—*Trade Catalogue of Flower and Vegetable Seeds.*

Books (Gardener).—There is no such work as that you name published at this office.

Market Punnets (J. Lyell).—If you inquire of some of the salesmen at the Manchester fruit and vegetable market they will inform you if the punnets are sold there; if they are not, you can obtain them from Mr. Munro, salesman, Covent Garden Market, London.

Large Apples (Inquirer).—Warner's King and Gloria Mundi are two of the largest. At the Hereford Show held last month the first-prize five fruits of the former weighed 7 lbs. 3 ozs.; second, 5 lbs. 7½ ozs.; and third, 4 lbs. 12½ ozs. In 1879 Gloria Mundi secured the first prize, the five fruits weighing 5 lbs. 10½ ozs. Warner's King is the most useful of the very large late Apples, the tree being a good grower and excellent bearer.

The Scotch Champion Potato (S.W.).—It is almost or quite impossible for anyone to give a description of this variety to enable you to distinguish it from others grown under the same name, especially if there is a close similarity between them. The tuber closely resembles that of the White Rock, is roundish in form, with deep eyes; the haulm is tall, erect, of a rather light green colour, with pointed leaflets, and continues green after that of the Roek has withered. You had better prove for yourself which is the best variety and discard the others, or purchase seed from a reliable source.

Mealy Bug on Vines (J. B.).—Read our reply to another correspondent, under the heading of "Vines in a Stove." The house must also be thoroughly cleansed, every portion of woodwork being washed, and the surface soil, if any, removed and fresh added. The plants and pots must also be carefully washed and repotted, or surface-dressed with fresh soil. After all you can do, however, in this respect the insects will appear again, and it is only by assiduously watching for them and perseveringly attacking them that the pest can be extirpated. Peruse carefully the several articles that have appeared on destroying mealy bug in the back numbers of the present volume, and follow the practice recommended that is most applicable to your case.

Sparmannia africana (Inquirers).—The leaf and flower you sent are

those of the old and attractive shrub named above. It is a native of South Africa, whence it was introduced to this country towards the close of the last century. The first plants or seeds were forwarded to Kew, and from these other gardens obtained their supply. The plant is named in honour of a Swedish traveller who introduced it. For flowering in winter and spring under culture in pots it is most effective, the growth being free, and the large trusses of flowers produced in profusion.

Growing Grapes without Fire Heat (F. W.).—That they can be so grown your own successful experience proves, as also does that of other cultivators. The sense in which your letter was understood by a correspondent as misleading was that there was no indication of the locality, and it is obvious that the Isle of Wight and the southern districts of the kingdom generally offer far greater chances of success by this mode of culture than do the much colder northern counties. We have seen Grapes fairly ripened during a favourable season in a house having no artificial heat in Nottinghamshire; but last year, although every effort was made to aid the ripening of the crop, it was worthless. A house is rendered doubly valuable when means are afforded for excluding frost and giving a little assistance to the Vines during their early stages of growth; the Grapes may afterwards be grown, if required, and ripened without fire heat, the locality and season being favourable. Much disappointment has been experienced in cold districts by orchard houses having been erected with no means of excluding frost from them in the spring when the trees were in blossom, and after all the expense that had been incurred good crops of fruit could not be produced until the structures were heated. Growing Grapes and other fruits in unheated houses is entirely a question of locality. In one district the plan will answer, in another it is quite unreliable; and the safe mode—the most economical in the end, and the most profitable—is to afford the means for supplying artificial heat when it is necessary.

Melons (J. E.).—Read's Scarlet-flesh and Eastnor Castle Green-flesh, which you name, are excellent free-growing and good setting varieties. It is not the nature of Melons to continue setting and swelling their fruits over a long period; but if an early crop is ripened and cut the same plants will, under good cultivation and attention, produce a second crop; but amateurs do not often accomplish this satisfactorily. It is no trouble for us to answer inquiries when we can do so usefully.

Propagating Frame (Amateur).—The frame to which you refer is very useful for raising seedlings and striking cuttings, and if you have space in your greenhouse for one you will find it of service to you. The value of the frame, however, depends on its management, and a fair knowledge of gardening and ordinary intelligence are only needed to work it satisfactorily. We know it has been employed with success by many amateurs, and only one failure has been brought to our notice, and this we suspect was not wholly the fault of the frame.

Uses of the Catalpas (W. Harris).—The species forming the genus *Catalpa* are more remarkable for their beauty than by the possession of particular economic qualities. *C. syriaca* is a handsome North American tree that thrives freely in this climate, and when in flower is unsurpassed. They are mostly of quick growth, and have a light grey-coloured wood of rather fine texture, and when well seasoned is said to be durable. It also admits of being very highly polished. The bark has the reputation of possessing stimulant and tonic qualities.

Soil for Cucumbers (Cucumber Soil).—As the soil you name is "very good" we think you will succeed in your object. Mix with it now a portion of soot, as much burnt refuse as you can obtain, a little decayed hotbed manure, with a sprinkling of the fowl manure, and produce a heap as rough and open as possible, as fine, close, and fibreless soil is not good for Cucumbers. If in addition to this, which may form the bulk of the beds, you add layers of fresh turfy loam and manure as the roots protrude from the surface, you ought with otherwise suitable culture to succeed in growing good Cucumbers.

Manuring Apple Trees (Old Subscriber).—If the trees are not too old for renovation you cannot do better than carry out the plan you propose. You may apply the liquid of the strength you name in sufficient quantity to penetrate the soil to the depth of at least 2 feet. Merely wetting the surface to a depth of an inch or two will be of little avail, neither will much good be done by pouring the water close to the stems or within a few feet of them only. The roots have a greater spread than the branches, and their extremities are the most active in gathering food; the application must, therefore, be complete and thorough as far as the roots extend. This soaking, even without removing the grass, would do good; but if the trees make but little growth they would be still further benefited by removing the turf and a little surface soil also, adding an inch of fresh soil next the roots, burnt refuse of any kind being excellent, and a thick covering of rich manure, the liquid manure to be applied before spreading on the fresh compost. Remove any dead or cankered wood, and if the branches are covered with lichens dust them when wet, as after a drizzly day, with freshly slaked lime, or dress the stems and large branches with strong brine.

Dwarf Roses (A Subscriber).—The following are all good varieties; but the last named, and possibly some of the others if they grow strongly, may need pegging down. Prune them all rather closely in March, and the following year, instead of pruning so closely, peg down some of the stronger growths, and you will have a fine display of flowers. Marie Baumann, Charles Lefebvre, La France, Baronne de Rothschild, Louis Van Houtte, Etienne Levet, Alfred Colomb, François Michelon, Marie Rady, Madame Victor Verdier, Marquise de Castellane, A. K. Williams, May Quennell, Marie Finger, Star of Waltham, La Rosière, Général Jacqueminot, Duchess of Bedford, Duchesse de Vallombrosa, Mrs. Baker, Madame Lacharme, Sir Garnet Wolseley, Mons. E. Y. Teas, and Gloire de Dijon.

Vines in a Stove (A Twelve-years Subscriber).—If you must grow stove plants, and keep the house warm and moist throughout the year, you ought not to be expected to grow Grapes in the same house. Vines require much more air than do stove plants, also a period of rest in winter, and these they must have or they will not produce good Grapes however suitable the border may be. It appears you are able to afford the Vines some rest this year, and by all means do so; it will benefit them, but they cannot be satisfactory if they have not rest, the wood being matured, every year. Greenhouse plants and Vines may, with good management, be grown successfully in the same structure, but stove plants and Vines cannot, as the former require a high temperature, considerable atmospheric moisture, and often but little ventilation—conditions that are totally unsuitable for Vines. When Vines and plants are grown together it is often an advantage to have the houses so constructed that the Vines can be trained outside after the wood is matured, and there remain, being protected if necessary for three or four months. You cannot have any better instructions for eradicating mealy bug than have appeared in our columns during the last six months. When the Vines are pruned, dress them thoroughly with a strong solution of soft soap or Gishurst compound, 5 or 6 ozs. of either being dissolved

in a gallon of water, adding thereto an ounce of paraffin, the wash to be used as hot as the hand can bear and applied with a brush. This scrubbing, thoroughly done, is more effectual for cleansing Vines than painting them with any pigment. If you have mealy bug on the plants the insects are almost certain to spread to the Vines in the same house.

Vine Shoots Injured—Galvanised Wire (Civis).—The spots on the shoots are not the eggs of insects. The bark appears to have been injured as if the Vines had been seriously attacked with thrips. The wood is not well ripened. We presume you removed most of the injured portions when pruning, and you cannot do better than wash the rods with the solution recommended to other correspondents. Instead of most of the writers on the subject of galvanised wire disagreeing with you, the majority of them confirmed your statement as to the wire being injurious. Injurious some of it undoubtedly is, and especially in certain positions. You will find some notes on the subject in the present issue, and others will follow which we think will not be uninteresting.

Heating a Greenhouse (H. A. M.).—Your question is not sufficiently clear. As we understand your letter you wish to form a greenhouse on the top of your house, to be heated from a kitchen range 18 feet below. There will be no difficulty in this. If you send 3^d in postage stamps to the publisher, and ask him to send you No. 769 of the Journal, you will find an illustration of a viney heated from a kitchen boiler; and if you adopt the same principle, taking the flow pipe from the top of the boiler direct to the greenhouse, then round it, the return passing down by the side of the flow and into the bottom of the boiler, the water will circulate. Without knowing the size, length, and height, both at the front and back of your proposed greenhouse, or to the apex if it is a span-roof, also the aspect and exposure, no one can inform you how much piping will be required to heat it.

Zonal Pelargonium Guillon Mangilli (X. X.).—Since Mr. Taylor's commendatory notes of this variety were published on page 544 we have received several letters asking where plants can be purchased, as the writers have not been able to find the name in catalogues. We know the variety to be an excellent one, and those who have plants of it for disposal would do well to advertise them. Mr. Taylor is not a nurseryman, and we are not justified in forwarding letters to him from those who wish to obtain plants of the variety in question.

Names of Fruit (No Name).—1, Not recognised; 2, Fearn's Pippin; 3, Winter Colman; 4, Beurré d'Aremberg. (E. Banks).—1 is Cobham; 2, too shrivelled for identification.

Names of Plants (Inquirers).—1 is *Sparmannia africana* (see above); 2 very much shrivelled, but resembles *Preunthes elegantissima*. (C. J. A.).—The specimen was quite insufficient for identification, but it is not *Libonia floribunda*. Send a flowering spray. (R. P. O.).—The flower was much crushed, but is like *Oncidium cheiroporum*, which requires a stove temperature. (Prima).—The scarlet flower was so much shrivelled as to be almost unrecognisable, but we think it is *Bouvardia Hogarth*. Dry cotton wool is the worst material in which to pack flowers, as it extracts the moisture from them. We do not undertake to name varieties of florists' flowers, and the blooms of *Chrysanthemums* sent are far too imperfect for identification; we can only say No. 1 resembles James Salter, No. 2 Mrs. George Rundle, and 3, Gloire de Toulouse. (J. S. Upex).—*Zygopetalum Mackaili*. (Mrs. Axe).—It is impossible to identify the shrub from the few shrivelled leaves you have sent.

POULTRY, PIGEON, AND BEE CHRONICLE.

THE CULTIVATION OF LAND BY ANIMAL POWER.

STEAM culture is now made available to a much greater extent than at any former period, and there is no doubt that it will increase in the estimation of the home farmer under certain circumstances, although there are but few home farms that contain arable land sufficient to make it good policy to obtain and maintain a full force of steam tackle to do the cultivation thereon without a considerable force of animal power in addition. Again, upon small farms, such as those which have previously employed two or three teams of horses, steam power is now often called in to supplement the animal power without any estimate of it or proportionate reduction of the number of animals employed, it being considered best to hire steam as occasion may require; but, owing in a great measure to the fickleness of our climate, the demand for hired steam tackle often occurs in many directions at the same time. Now this fact makes it very difficult for the home farmer to know how and to what extent the animal power of the farm can be diminished. This being true, it is fast becoming advisable to further consider how far and in what way the animal power on the farm may be increased, or so changed and managed as to be able to do without steam power, and to accomplish the various work connected with tillage of the land in good season and in a practical manner, thus avoiding any of the disadvantage and disappointment of not being able to secure the use

of steam power at the periods when most necessary. There are two periods of the year when it is especially important that the cultivating power should be equal to the work to be done—namely, the spring seed time for Lent corn, the preparation for early root crops, and again the autumn cultivation of corn stubbles during and immediately after harvest.

We have now arrived at the point of our subject, as to how far the animal power of the farm can be made efficient for the cultivation of the land at every season of the year, for it is positively intolerable that the success of our tillage and seeding of the crops in due season should be dependant upon the occasional use of steam power in aid of the animal power, unless it can be obtained to a certainty when most required. This is extremely important as a matter of farm management; for let us consider how short is the period when the extra work for steam power is required either in the spring or autumn, for the time in our climate cannot often be numbered by weeks—in fact, frequently only by days, when the weather proves favourable or otherwise. The home farmer will therefore be enabled to see the advantage of a sufficiency of animal power to make him independent of hiring steam tackle upon farms not of sufficient acreage to employ steam tackle as the chief motive power on the farm. The next point is, What resources we have in animal power? For the past twelve or fifteen years the use of oxen has declined except in certain districts, where they are still held in estimation, and used by the farmers for tillage of the land. Horses have, however, during the same period advanced in price, although upon a great many large farms steam tackle has displaced a considerable number. In the absence of steam power we have to choose between horses or oxen, or some of each, and we have particularly noticed that points for discussion have arisen between their advocates as to the merits of both kinds of animals for farm work; but it has generally been put as follows:—“Horses *versus* oxen.” We see no reason why the matter should be discussed in this way, for whenever we have had an opportunity of joining in a discussion where our opinion has been requested, so far from placing them one against the other, we have for many years and up to the present time advocated the use of both, except under peculiar circumstances. The points, then, which naturally arise before we could state the proportion in which horses should be used depend upon a variety of circumstances, such as the soil and climate, the facility of obtaining good animals, and many others, which will come into notice during the statements we shall have to make before concluding the subject.

In certain districts of the kingdom no oxen are used for tillage work in consequence of the manner of using them, and their value in work as compared with horses is but little understood; we therefore propose to give the opinions of farmers who do use them, in order to draw some conclusions as to what improvements may be made in the management of oxen during the working period. Before doing this, however, we wish to call the attention of the home farmer to the mode of management at an early period of the present century, so that if any points are suggested worth our notice we may avail ourselves of them to a certain extent. About thirty years ago we were present at a “farmer’s club,” when the subject of “The advantages of working oxen as compared with horses for farming purposes” was introduced by a practical farmer, who commenced his observations by stating that “he had employed oxen both for tillage work as well as waggon work for a period of over forty years. He had worked seven oxen in a broad-wheel waggon for a number of years, fetched thirty-five sacks of Wheat a distance of ten miles, and this had induced others to follow his example. When he worked them on the roads the animals were cued or shod, otherwise whilst cultivating the land they were worked without shoeing. On the last farm he had in occupation, consisting of 600 acres, he kept from five to seven horses and sixteen oxen, the latter ploughing 3 acres per day, and other work of tillage in addition; the oxen, being fed only upon grass in summer and roots and straw in winter, only cost about 4s. per week, being about half the cost of horses’ keep. The oxen and horses were each broken-in to harness at three years old. The cost of a three-year-old steer was about half the cost of a three-year-old colt. Allow the latter to live to the age of fifteen years you get twelve years work from him—he then dies, sinking the whole of his value; whereas the oxen, although kept at the cheapest rate, will gain £1 per year. The casualties on oxen are very trivial compared with horses, for he had only lost five oxen during a period of fifty years; the cost of harness was much less than for horses, less for the veterinary charges; neither was shoeing required, except for road work. His mode of working oxen was to have six for a plough, using three at a time for half the day, working from 6 A.M. to 6 P.M. After this statement a resolution was passed, “That out of every three teams of horses generally

one may be discontinued, and a team of oxen substituted instead, to the great advantage of the farmer; also, that on many two-team farms a team of oxen may be worked.”

Having now related the ideas which prevailed some thirty-five years ago we will refer to the subject as matters are at present, and give such recommendations as are now approved by practical farmers in various districts, but especially the western and south-western counties. Various breeds of cattle are used for labour in the field, and in our estimation they stand thus—Herefords first, then Sussex, next Devon, and lastly Shorthorns. On small occupations, where oxen would be used chiefly, they cannot be bred conveniently. They may, however, be purchased at three years old, and broken-in for work if required for constant use throughout the year. The manner of yoking the oxen in early times used to be by fastening the draught gear to the horns; in some cases they were yoked to the tip, and in others to the root of the horns. At the present time, however, the ox is usually made to draw by the shoulder like a horse; his head is then free and his motion natural, and in this way, too, they are more easily broken-in to labour. Oxen are not so well adapted for all soils and work as horses. We only recommend them as supplementary animal power in the absence of steam tackle. Upon the home farm, or any farm up to 300 or 400 acres of tillage land, they are best purchased at four years old, and having been broken to work; and they should be in good condition, fit to go into constant labour at once. When the oxen are substituted for steam power, as we recommend them, they are not required during the whole year; and therefore, instead of sending them into the straw yards for winter quarters as working animals for the next year, we prefer after autumn tillage and Wheat-sowings are finished to box them and feed for beef, making fresh purchases when required. The farmer will notice that we do not propose to make them the constant labourers on the farm like the horses. We resort to oxen in the spring to commence the tillage after an adverse autumn, such as we have had for several years past, when the autumn fallows could not be completed; otherwise we take them up on the edge of harvest, in order that during the harvest and until Wheat-sowing is completed they may assist the horses to cultivate the Wheat stubbles and all the land intended for Barley and early roots in the succeeding spring. We prefer to purchase oxen of full age and power, in order that, like the horses, they may be worked two to a plough without a driver, and in this way they will plough and do the work, harrowing and rolling, and take their part in the work, the same as the horses. To enable them to do this they must be fed at the same cost as the horses, and cared for by housing and grooming in the same manner, so that they may not only be able to do the work, but improve in condition and value at the same time, to be fed for beef in the winter months. Maize as well as oats are good flesh and muscle-forming food. Our importations of oxen from Spain and Portugal are excellent illustrations of what may be done by working and Maize-feeding simultaneously. There is, however, one drawback: when a worked ox draws from the shoulder it hardens the meat and deteriorates the value of the forequarters of beef, which shows the only advantage derived by yoking from the horns.

In making some comparisons between the horse and the ox it should be noted that the ox gains in value during work; but the horse diminishes unless he is sold at six years old, and having been broken to work at three years of age. The cost of horse harness is much greater, the veterinary charges, the shoeing charges greater, and the danger to life and limb are greater than with the ox. Oxen, however, are best adapted for dry friable land, such as loam, sand, gravelly soil with only small stones in it, and then they will not require cueing; but on strong loams with large flints thereon they cannot be worked regularly without cueing. In relation to cost of oxen: For the past ten years a pair of oxen in good working order have cost little more than one horse of good size and power fit for two-horse-ploughing work. We shall not enlarge upon the subject further at present, but may refer to it hereafter on the “Work on the Home Farm.” We ask the home farmer to consider the advantages which oxen afford him as a supplementary tillage power, when from any circumstances he may be unable to obtain the full advantage of immediate access to steam tackle.

WORK ON THE HOME FARM.

Horse Labour.—This now consists of finishing the fallow ploughing on those farms where it has not already been completed, in order that the land may receive the full benefit to be derived by alternations of frost and rain. The remainder of the land to be sown with Wheat after roots fed should be ploughed and sown simultaneously as fast as the sheep have cleared the land. Some farmers object to sowing Wheat in January, but we have always found the earliest season is the safest if 3 bushels of seed per acre are sown, as the crop does not suffer so much from weeds as when sown later in the spring.

Some of the horses may be employed in carting gravel to roads, carting earth to heap from the roadsides, banks, and borders of the fences, to remain there until quite mellow and weeds and grass roots entirely decayed. It will then be useful in placing at the bottom of pens where cattle and pigs are fed, and also at the bottom of cattle boxes and yards with the manure accumulating. In this manner the earth does not weaken the manure, but absorbs what would otherwise be lost. When carted away and cast up together they make one of the best composts for dressing grass land that can be manufactured upon the farm. This leads us to the subject of winter management of the park land or pastures, for it is not uncommon to find tufts of grass which have been left and refused by the cattle. It is therefore important how these are to be disposed of—whether to pass the scythe over, or to put on the land a few poor cattle as gnawers and to eat it down, because well-fed cattle in other respects cannot be made to touch it without great loss in condition. As we have before now observed, they will eat it better when salt has been laid on. Whatever plan may be adopted, it is still better not to have any of this rough food left on the pastures, which raises the question, How is it to be avoided? We reply, The home farmer should remember that the cause of these coarse grass bunches is the quantity of cattle droppings that is left undisturbed during the summer months. We advise that about once a week the droppings should be collected and taken to a heap of earth, in order to make a compost for dressing the grass land, or otherwise a person employed every few days to knock and spread the droppings during the summer. In this way we may have the pastures fed as smooth and as close as the turf on a cricket ground. This is not only best for the pastures, but it is almost the only way to make the parklands ornamental and sightly as they should be.

Hand Labour.—The odd horse and cart must attend to the work of fetching hay and straw for the dairy cows and fatting cattle, also roots from the storeheap or from the fields where grown, hay and straw for feeding being never better than when cut fresh from the ricks daily. Hedging, banking, and ditching will be going on in the enclosed districts, also cutting the undergrowth in the woodlands. Planting hedges and repairing live fences should now be done. The most difficult part of live-fence repairing is where trees grow on the banks or near, in which case the usual scrub wood dies away. We recommend for planting under trees the Myrobalan or Cherry Plum (*Prunus Myrobalana*), and by planting these the live fences may be kept entire without the unsightly wood fencing, which is also costly to keep in repair. Iron hurdles may be used, but they destroy the uniformity and are otherwise objectionable.

Shepherds now are variously employed, for horned Somerset ewes have lambed and only need the usual attention. The Dorset downs are beginning to lamb, and folds or yards should now be made up comfortable and well littered in a sheltered position. There is no better convenience for a lambing yard than when near an old barn, so that lambs or ewes which require extra attention may be cared for in the hospital barn. The Hampshire downs will commence lambing in January, and their lambing quarters should be prepared—the sooner the better, as the ewes may be fed with hay and straw in them at night some time previous to the lambing. The only objection seems to be in the tendency to lameness amongst the ewes when fed in yards in wet weather. It is well to place some earth at the bottom of the dead fold, and the sheep will lie drier, especially if the land is a little sloping.

The fatting sheep, the horned ewes and lambs, should now be fed with cut roots in troughs; and, in order to insure a continuation of the root supply, not less than ten days' or a fortnight's provision of roots should be previously cleaned and prepared ready for cutting, in order that bad weather may not interfere with the women's or men's work in preparing and heaping the roots. It must be remembered after sheep have been fed at the troughs they could not be fed otherwise except at serious loss and inconvenience in many respects. The food for horned ewes and lambs will be cut Swedes for the former and cut Carrots or Cabbage for the latter. In both cases cake and bean or barley meal should be strewed over and mixed with the cut roots, but the roots should be passed through the cutter twice for the lambs. The ewes may have broad Clover or Saintfoin hay, but the lambs should have Dutch Clover or mixed Trefoil hay, as it is finer and softer, and they can eat it better at an early age. We recommend that all Swedes and early roots should be looked over by the women. They should also fork out all roots of Couch grass, Docks, and other root weeds, as these are easily seen when the leaves of the roots are fallen; and we would request the home farmer to remember that the first cost in the removal of Couch, &c., is always the least.

TOY PIGEONS—THE TRUMPETER.

THERE is no variety of Pigeons which within our own memory has so much changed, and, from a fancier's point of view, been so much improved, as the Trumpeter. We say from a fancier's point of view, for, looked at aesthetically, we think the old English type of Trumpeter was decidedly a prettier bird than those of the Russian style at present exhibited. The origin of the Trumpeter's name is not so obscure as that of most fancy Pigeons. Before playing to the hen the cock bows himself down and makes a long hoarse coo not very unlike the sound of an indifferent trumpeter.

We have had small African Doves whose gestures and notes are very similar. We possessed a flight of white English Trumpeters in childhood twenty years ago; extremely beautiful they were, active on the wing, like their relations the Swallows, and altogether much lighter and more agile than the exhibition Trumpeters of to-day. They bred well and were good mothers, indeed a variety which might well be kept for their prettiness and useful qualities as table birds combined. Some time later, about fourteen years ago we think, a wonderful importation of Russian Trumpeters arrived in this country. They were introduced by Mr. Baily of Mount Street, and were, we understood, brought with the greatest difficulty across the Steppes from Siberia. Strange it seems that so savage a region should afford a race of birds which must undoubtedly long have been bred with care up to an artificial standard of merit! Many of them perished on the way, but those which arrived on English soil perfectly astonished Pigeon fanciers with their size and their wonderful development of Trumpeter points. As soon as they had sufficiently recovered from their travels to be exhibited they at once drove the old type of Trumpeter out of the field. For a time it was attempted to have separate classes for birds of the two types; but this plan soon failed, inasmuch as there was no real distinction between them, the only difference being great development of already acknowledged points in the new birds. The Russian breed has now quite superseded the other as exhibition birds, and those shown and seen in good lofts all mainly owe their origin to this or some other importation.

The points of the Trumpeter are not many; but to be understood it should be seen, and almost defies description. The Trumpeter is a heavy bird and now by no means active, for the feathers of its rose, like those of the Poland fowls' tuft, much impede its vision. It has a shell or crown at the back of its head, such as we have described when speaking of the Nun, which should come as much round the head as possible on each side. One of its most distinctive points, however, is the rose—a tuft of feathers rising from the root of the beak. This in the old birds merely formed an irregular tuft, but in the modern Trumpeter it is of immense size and completely circular, almost covering the beak and the whole of the head within the crowns. Great weight is given in judging to the size and regularity of this rose. The other most characteristic point is foot-feathering. A good Trumpeter is heavily feathered or hocked on the leg, and then has beautiful flat feathers extending like little wings from the feet. These two latter points should in our opinion be equally considered, and not all given to rose, which we have frequently seen some good judges do. The colours of Trumpeters were formerly many, the Whites being the best. The great Russian importation were nearly all mottled—i.e., black and white, or black; these two colours have consequently become the most popular, which we regret, for the Whites are extremely beautiful. At the last Crystal Palace Show, however, two magnificent Whites were shown, and quite held their own against all colours. It is not easy to imagine much more beautiful Pigeons. As with some other white Pigeons, we believe that young birds are often speckled, and only moult out pure white after two or three years. Of course this is not the case with such old-established breeds as White Fantails, but the Trumpeters and Jacobins, the various colours of which have been much interbred, are seldom pure white their first year. Yellows and Reds were formerly known, and we have seen a Blue Trumpeter depicted on a very antique mosaic; but they have now disappeared, and to reproduce them of a type to compete with the wonderful mottled birds which we now see in the prize pen, would take much time. Of course, care is requisite to keep the foot feathers of Trumpeters in nice order and condition, which adds greatly to their beauty, and which is often not sufficiently appreciated by judges. Trumpeters are fitted rather for the aviary and loft than to fly at complete liberty, for few Pigeons so easily fall a prey to cats. They breed well when not too highly bred, and in their improved state are a profitable variety for domestic use.—C.

BELFAST POULTRY SHOW.

THIS, the leading Irish Show, was held on the Wednesday and Thursday of last week. Both in the number of entries and in the quality of the birds shown, it was considerably ahead of former years. The Victoria Horse Bazaar is a large well-lighted building, very suitable for a show. The arrangements were admirably carried out under the direction of Mr. Waters, who is a model Secretary, and a Committee of fanciers well up to their work and with their hearts in it. The poultry were all on the lower tier, the Pigeons above; and as the floors of the Pigeon pens did not cover the back part of the tops of the poultry pens, a rather trying cross light was the result. Mr. Leno judged the poultry, a task which made a pretty hard day's work for him; Mr. Fulton the Pigeons. At this Show the attendance

is never very large, so that the Committee have to depend chiefly upon the entry fees to make up the prize money. There were many cups presented for competition, but the class prizes were merely £1, 10s., and 5s., with an entry fee of 3s. 6d. The success which has hitherto attended the efforts of the Belfast fanciers affords proof that exhibitors do not much regard the amount of the prize money offered; and that the knowledge that their birds will be properly cared for and judged by competent men, is a sufficient inducement to lead them to exhibit.

DORKINGS opened the poultry classes, and were upon the whole a wonderful collection. There were five cups or special prizes offered for this breed; No. 1 for the best Dorking in the Any age classes went to Messrs. Smyth for the cockerel first in the coloured Dorking cock class. Cup No. 2, for the best pen of coloured Dorkings in the chicken class, also went to Londonderry, won by the first-prize pen of chickens. The cockerel in this pen also took the third special prize, a medal offered for the best coloured Dorking cockerel or pullet in the Show, while the pair completed the Messrs. Smyth's list of trophies by winning the fourth special offered for the best pen in the chicken class. The fifth, a cup for the best pen of Silver-Grey chickens, went to Mr. Shaw's third-prize pen. Except in the case of the Brahmas which (in consequence of the entries being guaranteed to be not less than eighty by a Dublin fancier) had separate classes for adults and chickens, the general classes were open to birds of any age. Dorkings and Cochins had, however, chicken classes in addition to the general classes. *Coloured Dorking.*—Cocks (six) beyond the winners contained nothing very special. First, cup, and medal (Smyth) was one of the best cockerels we have seen this year, large and square in frame, well set down on his legs, moderate in comb. Second (King) a fine old bird, not quite in condition, and rather loose in comb. Third (King) an old bird of moderate quality; h.c. (Smyth) a promising young cockerel; h.c., Herdman. *Hens* (nine) were one of the best classes we have seen of late. First (King) a grand massive hen good in all points. Second (Herdman) also a very fine hen, rather better in colour but not so short in leg as first. Third (Smyth) very fine in quality and very good in feet, but not so large as the other two; h.c., Smyth (2) were both winners at the Palace as pullets last year, but not yet fully grown; h.c., Herdman; c., Smyth. *Any Other Colour Cocks* (eight) were not a very remarkable class, and were all Silver-Greys. First (Ovens) a large bird for a Silver-Grey, but yellow on back and heavy in comb. Second (Mulligan) rather deficient in size, also rather yellow for a cockerel. Third (Shaw) a very shapely bird, short in leg though rather gone in the feet; h.c. (Miss Drevar) the best colour in the class, but too small and heavy in comb. *Hens* (nine) were a very fair class. First (Shaw) a very shapely hen of good size and beautiful colour, but rather dark in feet. Second (Metge) another good coloured hen, not so shapely as the first, and also inclined to be dark in feet. Third (Ovens) large but brown; h.c., Mulligan, Charley. *Any Variety Cockerel and Pullet* (fourteen).—An extraordinary class which would have been a credit to any show. First, cup, and special (Smyth) a very grand pair indeed of coloured birds which have not, we believe, been out before, and would deserve all that could be said in their favour. £40 was, we believe, offered and refused for the cockerel the first day of the Show. Second (Smyth) another very fine pair of similar style, sold we believe for £25. Third and Silver-Grey cup (Shaw) a neat pair of Silver-Greys, the cockerel very clear in colour and good all round; v.h.c. (King), the cup Palace and Birmingham cockerel and a pullet that has won prizes at all three leading shows, but fairly defeated here; v.h.c. (Smyth), the cockerel the Dairy Show winner; h.c., Shaw.

BRAHMAS, strange to say, just came up to the guaranteed number—eighty. *Dark Cocks* (ten) contained some good birds. All three prizes went to Mr. Comyns. First being the bird h.c. at Birmingham greatly improved by the fortnight's growth of feather. Second the third Dairy Show cockerel of last year, also improved in condition since his v.h.c.'s at the Palace and Hull. Third the Cambridge cup cockerel of last season; c., Ashworth, Comyns. *Hens* (eleven) were hardly judged to our taste; all the honours again went to one exhibitor (Mr. Comyns), who was very successful at this Show. The Judge considered the class a good one. First and Brahma cup was, we believe, a fresh one; she is well marked, but heavy in head and not quite clear in colour, for which reasons she might well have given way to second, the Birmingham h.c. bird, now moulted out and in fine form. Third was one of the recently purchased Shuter stock, very clear on back and wings but failing in breast; v.h.c. (Comyns) a clear Silver-Grey, well marked but small, and comb awry; h.c., Comyns; c., Ashworth. *Cockerels* (fourteen) were not remarkable as a class, but there were some good birds in it. First (Erskine) good in size, shape, and colour, but very heavily hocked. Second (Comyns) the v.h.c. Palace bird, looking yellow in the trying/cross light already referred to. Third (Charley) a shapely bird, neat in head, but not large and rather short of feather; h.c. (Comyns), the Palace sixth; c., Comyns. *Pullets* (thirteen) were a good class, the winners were we believe, chiefly of Miss Shuter's stock, shown by Mr. Comyns, who scored first, second, third, and three h.c.'s with his six entries. The third was in the same position as at Hull, and one of the h.c.'s was similarly honoured at Birmingham; h.c. (Henshall), very nice in colour and fair in marking; h.c., Ashworth. *Light Cocks* (six) had nothing of note beyond the winner. First (Birch) a very grand bird in all points except his comb, which was far too large. Second (Herdman) much weaker in head and good in shape and colour, but

not nearly so large as the winner. Third (Birch) a little hollow in chest and heavy in comb, otherwise a good one. *Hens* (nine) showed the common failing of impurity of colour. First (Birch) a very massive shapely hen, too warm in colour and hooked. Second (Dugan) another large hocked hen neat in head, also showing a buff tinge. Third (D. Sullivan) small but clear in colour; v.h.c., Graham; h.c., Herdman, Bireh. *Cockerels* (nine) were moderate as a class. First (Birch) a medium-sized bird, good in all points except colour, which was rather warm on his shoulders. Second (Herdman) another neat bird, very dark in hackle and yellow. Third (Herdman) a fair all-round bird short of foot feather. *Pullets* (nine).—First (Birch) a good-sized shapely pullet, clear in colour and neat in head. Second (Herdman) also a good pullet, very fine in head. Third (Mercer) rather yellow on the shoulders and hocked, very neat in head.

COCHINS.—*Cinnamon or Buff.*—Cocks were a fair class of eight. First (Stoney) a Buff cock of medium colour and size, good in foot feather, without hock. Second (Robertson) a larger bird, not nearly so even in colour, and hocked. Third (Pye) a cockerel similar in stamp to the winner, but hocked; h.c., Thomson. *Hens* (seven) failed chiefly in colour. First (C. Brown) a large shapely Cinnamon hen, not very even in colour. Second (Robertson) a very fine pullet of the dark shade, more even in colour than first. Third (Thomson) large, but not so good in shape and mossy; c., Hand. *Any other Colour.*—Cocks (eight) were a good average class. First (Bright) a Partridge cock, very rich in colour, good in shape and foot feather, with moderate hocks. Second (Robertson) another good Partridge cock. Third (Millner) a White, rather loose in comb and his tail not good; h.c., C. Brown, Robertson. *Hens* (sixteen) were a good class. First (C. Brown) a Partridge, good in size and fair in marking of the old style, but not cushion enough and too much tail. Second (Robertson) another fairly marked Partridge, not so large as first. Third (Robertson) well marked but small; h.c., Millner (2, White); c., T. A. Bond (Black). *Cockerels and Pullets, Any Variety.*—A fair class only. First-and-cup (Pye) a neat pair of Buffs, the cockerel very even in colour, the pullet not so good in this respect. Second (Robertson) Partridge, the cockerel shapely and short in limb with fine foot feather, but with a few brown feathers on breast and hocked; the pullet good in size, fair in shape, excellent in marking and foot feather. Third (Bond) moderate Blacks; h.c., Mahony (Buff), ditto (Partridge), Bond (Black), C. Brown (Partridge).

SPANISH.—Cocks (fourteen) are always a strong class at Belfast, and though not quite up to the average this season were very good. First (Boulton) an old cock, large in face and lobe, but rather inclined to close up his eyes. Second (Begg) a cockerel, large in face and good in lobe, but his face not in show form. Third (Mulligan) a cockerel very good in quality of face and lobe, and this latter neatly rounded off—our choice of the class; h.c., Begg, long in face but narrow. *Hens* (thirteen) were another good class. First (Boulton) a hen good in quality of face and lobe, but hardly through her moult yet. Second (Mulligan) another good hen. Third (Mulligan) a pullet, a trifle narrow over the eye, but very large and smooth in lobe; h.c., Mulligan, Begg.

GAME.—Cocks (eight).—A good class for Ireland, which is rather behind in the Game fancy. First-and-cup (Chesters) a very fair Brown Red, good in reach and fine in head. Second (Chesters) also a stylish Brown Red. Third (Booth) Brown Red again, rather soft in feather; h.c., Graham (Black Red); c., Mason (Black Red). *Hens* (eight) were also a good class. First (Booth) a stylish Brown Red pullet in fine condition. Second (Mason) a Black Red, neat in head and hard in feather. Third (Chesters) Brown Red; h.c., Robertson, Booth (both Willow-legged Pile), Chesters (Brown Red).

HAMBURGERS.—*Gold or Silver-spangled Cock and Hen* (eleven) were only moderate as a class. First (Crawford) Goldens, fair in marking and rich in colour; the cock's comb rather heavy. Second (Pickles) well-marked Silvers, neat in head, but the cock rough in lobe. Third (Crawford) moderate Goldens; h.c., Maclean (Silver); c., Collier, Ashworth (2) (all Silvers). *Gold or Silver-pencilled Cock or Hen* (six) again only a moderate class. First (Pickles) Silvers, clear in lobe, neat in comb, and fair in marking. Second (Clegg) fair Goldens. Third (Maclean) Goldens, neat in head and lobe; the hen rather heavy in marking; h.c., Ashworth, and c., Maclean (both Goldens). *Black Cock and Hen* (seven) were not a remarkable class. First (Ross) good in style and colour, moderate in lobe and comb. Second (Ross) bright in colour and good in lobe, but the cock rather heavy in comb. Third (Ashworth) rather pink in lobe; h.c., Bamford.

FRENCH.—*Any Variety Cock and Hen* (seventeen).—From their numbers may fairly claim two classes next year. There were nine pens of Houdans, five of Crèves, one La Flèche, and one Courtes Pates. First (Connor) were Crèves; the cock, the best of the two, a large bird, good in size and colour, but rather heavy in comb. Second (Wither) Houdans, good in size, crest, and comb. Third (O'Kelly) a fair pair of La Flèche; c., Kettlewell, Brinkley, Carter (all Houdans); Lindsay (Crèves).

POLISH.—*Any variety.*—Cock and Hen (seven) were a good class.—First (Charley) Goldens, good in crest, colour, and marking, but not quite in condition. Second (Lindsay) another pen of good Goldens. Third (Henry) Goldens again, the hen very large in crest; c., Sullivan (Golden), Millner (Silver).

ANY OTHER VARIETY EXCEPT BANTAMS.—Cock and Hen (nine) were made up of Malays (five), Brown Leghorns (two), Sultans (one), Moorfowl (one). First (Anderton) Sultans of fair quality

Second (Brinkley) fair Brown Leghorns. Third (Robertson) a good pair of Malays; c., Peirse Kelly (2, Malays and Brown Leghorns).

BANTAMS.—*Game, Black or Brown Reds.*—*Cock and Hen* (ten).—First-and-cup (Hand) were a neat little pair of Brown Reds, good in style and close in feather. Second (Shenton) very good Black Reds. Third (Streatch) another neat pair of Black Reds; h.c., Anderton, Shenton, Surgenor, and C. Russell (all Black Reds). *Game, Any Other Variety.*—*Cock and Hen* (five).—First (Surgenor) very smart willow-legged Piles. Second (Anderton) the same sort. Third (Anderton) also willow-legged Piles, too large for our taste.

ANY OTHER VARIETY.—*Cock and Hen* (nine) contained some good birds. First (Dunkerly) a very evenly marked pair of Silver-laced. Second (Anderton) Black Rosecombs. Third (Dunkerly) moderate Gold-laced; h.c., Thomson & Harrison (Japanese), Law (Cuckoo), Connor (Black Rosecombs).

DUCKS.—*Aylesbury* (ten) were a good class, all the winners being fine pairs. First, Mullan; second, Charley; third, Sullivan; c., Mullan, Charley. *Rouen* (ten) were a very good class. First and cup for Ducks other than Pekin, Birch; second, McCartney; third, Booth; h.c., Mulligan, Robertson. *Rouen hatched in 1880* were a large class of seventeen, but contained nothing remarkable in merit. First, Birch; second, McCartney; third, Bridgford; h.c., Stoney, Bridgford, Todd (2); c., Kettlewell. *Pekin* (eight), in Ireland as elsewhere, seem to be making their way, and were a good class. First-and-cup (Birch) were best in colour and carriage and large in size; second (Birch) and third (Campbell) were also large good pairs; h.c., Peirse, Kelly. *Any Other Variety* only numbered three. Of these the first (Booth) were Mandarins, the second (Carleton) and third (Robertson) Black East Indian.

TURKEYS.—*Cock and Hen* (six) were a fairly good class. First (Birch) also took the cup for Turkeys and Geese, and the special prize for the heaviest Turkey in the Show, the cockerel turning the scale at 32 lbs. Second (Glen), the cockerel in this pen weighed 26 lbs. Third, Dugan; h.c., Todd.

GEESE (nine) were a very good average class. First and second, Birch; third, Mullan; h.c., Carleton, Robertson.

PIGEONS.

POUTERS.—*Blue or Black Pied Cock* (six).—First-and-cup (Wither) an excellent Blue in fine condition. Second (Thorburn) also Blue and very good. Third (Combe) Black, fine in colour and marking; h.c., Montgomery; c., Sproull. *Any Other Colour Cock* (seven).—First (Montgomery) very lengthy White, good limb and crop, and in good show. Second (Sullivan) a very fine Pigeon, giving first a fair run for place. Third (Kilroy) best condition, but lost to the winner in crop and girth; h.c., Thorburn and Wither; c., Kilroy and Millner. *Any Other Colour Hen* (seven).—First (Combe) a fine Yellow, a very scarce colour in Pouters now; an easy win. Second, Sproull; third (Sproull) a good Blue, not in show, flights crossed. Extra third, Thorburn; h.c., Wither and Henry; c., Millner.

CARRIERS.—*Cock* (four).—First (Montgomery) a stout Black, fine beak wattle; but Mr. Montgomery, we fancy, could show a better all-round one. Second (Dunkerly) another stout one, not so large in wattle as first. Third (Montgomery) a good Dun; c., Montgomery. *Hen* (four).—First (Montgomery) a nice stout hen, grand in length of face and beak, wants time for development of eye. Second (Montgomery) Black, good fair hen. Third (Montgomery) a Blue.

BARBS.—*Cock and Hen, Any Colour* (six).—All winners black and good in skull. First, Montgomery. Second (Montgomery) a well-known bird, looks cankered in ear. Third, Dowling.

SHORT-FACED TUMBLERS.—*Cock or Hen* (three).—Only three entries and good. First, Dunkerly. Second, Dunkerly. Third, Kidd.

JACOBS.—*Red Cock* (sixteen).—First-and-cup (Shaw) very good and close in feather, last year's winner and nicely shown. Second (Shaw) good skull and hood, mane, and chain. A hard Red to beat. Third (Shaw) a frequent winner; we have seen him in better feather; very compact and showy; v.h.c., Pyper and Dale; h.c., Shaw and Roberts; c., Shaw. *Hen* (fourteen).—First (Shaw) close and compact, but for general qualities we prefer second or v.h.c. Second (Shaw) a good hen and hard to beat; very compact, close, and of good shape. Third (Shaw) moderate; we liked the v.h.c. of same owner much better; v.h.c. (Shaw), fine head, colour, and nice hen; h.c., Pyper and Dale; c., Shaw. *Yellow Cock* (twelve).—First (Pyper) good colour, compact, and nice condition; wants more feather. Second (Jeffery) great in feather but looked slovenly; a fine stock bird. Third (Roberts) good colour, face, and short of hood; h.c., Pyper; c., Jeffery and Dowling. *Hen* (eighteen).—First (Dowling) a small Pigeon, short of hood, good colour and chain. Second (McGibbon) our choice for winner, a real good all-round hen; the only point wanting being size. Third (Pyper) a good hen; h.c., Jeffery Pyper (2), Dale; c., Coates, Shaw. *Black Cock or Hen* (twelve).—First (Jeffery) a grand all-round Black; one of the best, we believe the Palace winner; fine colour and all over good. Second (Roberts) would not show, but when roused looked well. Third (Shaw) a good hen, the Kilmarnock winner; v.h.c. (Shaw) a good little hen, Weyman and Buchanan; h.c. (Jeffery), good colour and hood; Young; c., Coates. *White Cock* (ten).—A good class. First-and-cup (Waters) a very grand White cock, immense feather and very short face. Second (Dalc) very short of feather. Third (Shean), very nice Pigeon, and we prefer it to second; only loses in size; h.c., Waters and Shean. *Hen* (eleven).—First (Dale) very long and close

in feather; a very bad face. Second (Shean) fine face, hood, mane, and chain; latter might be closer. Third (Shean) a fair hen; 516 (Waters) deserved a card; h.c., Waters, Weyman, and Buchanan; c., Waters (3). *Any Other Colour Cock or Hen* (seventeen).—First (Shaw) a fine Strawberry hen, excellent shape, and rare face. Second (Waters) very close but short of feather. Third (Shean) very long feather, yet a far better Pigeon than second; h.c., Shaw and Shean; c., Jeffery and Pyper.

FANTAILS.—*Cock* (eleven).—First (W. & R. Anderson) a short-backed bird, fine motion and good tail. Second (Connor) a good bird. We preferred c. (Loversidge), not in the best condition though. Third (Hunter) short of tail feather but very nervous. *Hen* (fourteen).—First-and-cup (Shaw) a grand hen and well deserved her place. Second (Warhurst) a very fine Blue hen, one of the best of the colour we have seen. Third (Loversidge) very large, but condition poor; c., Anderson.

OWLS.—*English Cock* (ten).—First-and-cup (Woods) a wonderfully headed Silver, an easy win. Second (Wardle) good Blue. Third (Wardle) good Blue; c., Bright and Thorburn. *Hen* (six).—First (Dunkerly) a very nice hen, wants time to develop, but will improve. Second (Dale) a nice profile. Third (Woods) fair hen; c., Woods and Dale.

TURBITS.—*Cock* (eleven).—First (Wardle) good Blue, fine condition, good in head, peak frill, bars. Second (Evaus) a Black, and a very good one. Third (Dale) fair Blue; h.c., Dunkerly; c., Gilmour and Thorburn. *Hen* (seven).—First (Woods) good Blue, well shown. Second (Thorburn) a very fair Red. Third, Dowling.

TRUMPETERS.—*Cock or Hen* (nine).—Grand class. First-and-cup (Hutchinson) a magnificent black rose, hood and foot feather superb. Second (same owner) a Mottle. Third (same owner) the best White we ever saw; h.c., Waters; c., Hutchinson. *Cock or Hen bred in 1880* (seven).—Grand class. First (Hutchinson) a fine Mottle, or what would be called a Splash in other varieties, but a wonderful Pigeon. Second, same owner; third, same owner; h.c., Hutchinson; c., Hutchinson.

DRAGONS.—*Cock* (seven).—First (Smith) good Silver. Second (McKenzie) grand-coloured Yellow. Third (Smith) Blue. *Hen* (five).—First-and-cup (Smith) a grand Dragon, and easy win. Second (McKenzie) one of the best Yellows we have seen. Third (Smith) good Grizzle.

ANTWERPS.—*Cock or Hen* (eleven).—First (Jennings) Red Chequer cock; second, Wade; third, Dale; c., Millner and Wade.

FLYING TUMBLERS.—*Balds.*—*Cock or Hen* (eleven).—Good class. First (Woods) a good bird, clean cut, and poor flights; thighs, and colour black. Second (Magee) a very fair Blue. Third (Montgomery) a poor Black; h.c., Magee; c., Rogers and Thorburn. *Beards.*—*Cock or Hen* (six).—First-and-cup (Woods) a fine Blue Beard. Second (Woods) good bird. Third, Dunkerly; v.h.c., Edwardson; c., Rogers. *Self-coloured.*—*Cock or Hen* (seven).—First (Woods) Yellow, and good. Second (Crawford) a very sound Red. Third (Wardle) a good Black; v.h.c., Crawford. *Blue-barred or Any Other Colour.*—*Cock or Hen.*—First (Kidd) Black Mottle, in fine condition. Second (R. Woods) Yellow Mottle; we prefer to winner, as yellow is far harder to produce sound than black. Third (R. Wood) Red Mottle hen; h.c., R. Wood; c., R. Wood.

NUNS.—*Cock or Hen* (fourteen).—First (Young) Black, grand colour, hard flights, bib, and condition. Second (Dowling) good colour. Third Shaw; c., Jeffery.

MAGPIES.—*Cock or Hen* (eleven).—First (Dale) a wonderfully sound Red. Second (Bridgford) a Black, and one of the best we have seen. Third (Montgomery) good Yellow; h.c., Knox and Thorburn.

ANY OTHER VARIETY.—*Cock or Hen* (twelve).—First (Stoney) a rare Swallow, black. Second (Millner) a good Ice. Third (Shaw) a Fairy Spot.

MARGATE SHOW.

A SHOW of Poultry, Pigeons, and Cage Birds was held at the Hall-by-the-Sea, Margate, on the 14th and 15th inst. The weather was most unfavourable on both days, in consequence of which there were but few visitors, and it is feared the Show may not be a success in a pecuniary way. In classes where there were less than five entries the first prizes were withheld. The Show was, of course, a small one, being open to the counties of Kent, Surrey, and Sussex only. There were 177 pens of poultry and 135 of Pigeons. The total number of entries, including cage birds and dairy produce, was 425. Mr. Tegetmeier judged the poultry and Pigeons. His awards in the poultry classes were not satisfactory in some cases. The arrangements, under the Secretary, Mr. Lane-Sear, were excellent throughout.

Dorkings, Coloured.—The best pen (Goodwin) was only commended. Silver-Greys.—Cup (Cheeseman), a very good pen. The *Cochins* were poor on the whole. The Buffs numbered ten pens. The cup pen (Jenkins) were large, and good in colour and feather, but the hen was ragged and her wings slipped. Their tails were not neat or soft enough. The third-prize pen (Smart) contained a very large good hen, but she looked sickly about the head; this pen should have been second. **Brakmas.**—Dark, were moderate, the best pen, containing a beautifully pencilled hen, was passed over. First, Brown; second, Jones; third, Pearce. Light.—A much better class. First-and-cup (Cobb) good, but the hen was rather splashed with black on the back. The cock's hackle was heavily striped. Second (Ayliffe) and third (Windred) were nice

pens. A pair sent too late for competition by Rev. E. H. Morgan were far away from the rest. The cock was grand in shape, size, and feather. *Game* very good indeed; the cup went to a capital pair of close-feathered Piles belonging to Mr. J. Elgar. Among the *Hamburgs* the winners were a good pen of Blacks shown by Mr. Howlett. *Spanish* moderate, second (Shaxby) better than cup pen (Francis). *Minorcas* and *Polands* fair. The winning *Houdans* (Miss Nceme) were good. *Game Bantams* neat and good. The best pen in the class (Morgan), which were first at Canterbury last week, were only highly commended. In any other variety of Bantams Mrs. Brassey won the cup with a pretty pair of Dark Japanese. Mr. G. Sanger exhibited a curious pair of Jungle Fowls (*Gallus furcatus*) about the size of Bantams. The cock had a transparent-looking comb free from serrations, and curiously tinted with mauve, pink, green, and yellow. In the selling classes there was a splendid pair of White Cochin pullets (Todd), also a good pair of White-crested Black *Polands* (Howlett). Mr. H. Stephens was first in class for single cock with a very nice La Flèche cockerel.

The *Pigeons* were good on the whole and well judged. Among the Carriers and Pouters were capital specimens. All three prizes in the latter class went to Mr. Gill, while in the former Mr. Hall won in the two classes for Black or Dan, and Mr. Stephens in the "other coloured class" with a fine Blue.

VARIETIES.

MR. NORRIS'S DARK BRAHMA PULLET.—Many well-known fanciers have testified, since the Birmingham Show, that they were acquainted with this bird from her infancy, and have no doubt as to her being a chicken of this year. It is not in every case that a bird's age can be so clearly established, and we are very pleased that Mr. Norris has been able to adduce such overwhelming testimony. It seems to us to have been a somewhat similar case to the well-known one of the "Three Black Crows." Mr. Norris remarked to a friend, that "when the bird was running with a lot of his choice hens, she looked as large as any of them." This passed from mouth to mouth until it was magnified into a statement that Mr. Norris said he had found the pullet amongst a lot of old hens. This reached the ears of the protestor, and in an evil moment he paid his £1 and entered his protest. We were glad to see that some of the correspondents of a contemporary joined with us in reprobating the system adopted at Birmingham in reference to Mr. Norris's two birds. We hope never again to be witnesses of such discussions. Anything more detrimental to the interests of a healthful and innocent pursuit we can hardly imagine.

— THE A. B. C. POULTRY BOOK by Mrs. M. A. WILSON (Cassell, Petter, Galpin, & Co.) is, as its name indicates, arranged in the form of an encyclopædia. The authoress has, in addition to her own experience and knowledge, made use of Mr. Lewis Wright's large work on poultry as a source of information. The result is a very handy reference volume, containing a great deal that is useful in an easily accessible form. In such a work one could not expect the fullest detail as to fancy points, &c., or a very profound knowledge of the subjects treated upon, but the authoress seems to have grasped the cardinal points in most cases. Every young fancier should at once add this handbook to his poultry library.

— GOATS' MILK.—A meeting of members of the British Goat Society was recently held at its rooms, 446, Strand, to hear a paper by Dr. R. J. Lee, F.R.C.P. (one of the physicians to the Children's Hospital), on "Goats' Milk, and its Utility as a Food for Infants and Invalids." Professor Simonds presided. Mr. H. S. Holmes Pegler, Hon. Sec., reported that the Society now consists of 171 members, including the Duke of Wellington, Baroness Burdett-Coutts, Lady Cave, Lady Pigot, the Earl of Rosslyn, the Earl of Shaftesbury, Sir Henry Peek, Bart., M.P., Mr. James Howard, M.P., twenty-four ladies, twenty clergymen, and eleven doctors. Dr. Lee, in the course of his paper, stated that his sympathy in favour of a more general use of Goats' milk as a source of nourishment had been excited chiefly by a long acquaintance with the children of the working classes and their means of nourishment. In his own experience children fed on Goats' milk had thriven most satisfactorily, even when they had not thriven on cows' milk. He said the peculiarity about this milk is that the cream globules are smaller than in cows' milk; and the milk being more concentrated, the cream globules are contained in a more perfect state of emulsion, in consequence of which hardly any cream rises to the surface in allowing the milk to stand

for twelve hours or longer. This quality of the milk explained the fact that it was more easily digested than cows' milk. With regard to the use of Goats' milk for medicinal purposes, there was every reason in favour of making an extensive trial of it.

WINTERING BEES.

ADVANCED bee-keepers on the continent and in America are now alive to the importance of protecting their bees in winter. In America and some parts of the continent the winters are long and severe. In Great Britain the winters, generally speaking, are shorter and less severe, but more changeable and precarious. For fifteen years I have not failed to advise the bee-keepers of this country to cover their hives well and warmly in winter, and it is pleasant to know that the best practitioners of the movable comb system in this country are now beginning to winter their bees in hives kept warm by chaff. The chaff hive is an American invention, and is a very great and valuable improvement on all that has preceded it. Doubtless the clever active bee-keepers of this country will in time bring the chaff practice up to a point of excellence that cannot be surpassed. All bee-keepers should know and remember that bees suffer much from cold in winter, and that good coverings are beneficial and helpful in early spring when breeding commences.

I met a gentleman the other day who is an enthusiast among bar-frame hives and bees. His plan of ventilating the hives in winter in order to let out the moisture is very good. He removes the crown boards from his hives, and enlarges them at the tops by using ekes 4 inches deep. First covering the frames with some kind of porous cloth, he fills the ekes with chaff, which absorbs the moisture of the bees and carries it out of the hives. Bees in hives well ventilated and surrounded with 4 inches of chaff or soft hay, will have some comfort in wintry weather.

The operations of Nature and their habits of cleanliness prompt bees to leave their hives often in mild weather during the winter months, and in doing so there is frequently a great loss of life. Some winters and some days are more destructive of bee life than others. If the atmosphere and the ground around hives are cold when the bees come out in winter they are destroyed. The powers of flight in bees are lessened by cold; and even in summer weather bees carrying heavy loads are unable to fly home if a dark eloud chills the atmosphere about them. In their winter dances outside their hives many bees fall to the ground, become chilled at the first touch, and never rise. In this way hives lose numbers in winter and become weaker. If there come a sudden change or lower temperature while bees are flying about their doors in winter the sacrifice of life is very great. In large apiaries of hives standing close together the ground is thickly sprinkled with chilled bees after a flight; and in front of single hives scores of bees may be seen all but motionless—some on stalks of grass, some on twigs, quite helpless after making efforts to get off the cold soil that chilled them. At one time I thought that bees thus falling about the doors of their hives were diseased and could not be saved from death. However, I am now fully convinced that nothing is the matter with them but cold; and therefore I sweep them together in heaps, put them into flower pots, warm them into life and vigour at the kitchen fire, and let them fly home. The author of a German book on bees published a few months ago suggests the desirability of spreading some warm materials in front of hives in winter, to prevent the bees that touch the ground being quickly chilled into helplessness. This idea is a good one and practical. A piece of roofing felt, an old door mat, or a layer of sawdust under the flightboards and in front of hives, would doubtless save the lives of many bees. Some two years ago a Thorn hedge on the south side of my apiary was removed, and a brick wall 9 feet high was built in its place. About a dozen of my hives are wintered on the north side of this wall, which prevents the rays of the sun warming the ground near them. Far more bees are found chilled and motionless about these hives than about those in sunny positions. I am now fully convinced that sunny sheltered places are better than shaded ones for bees that are allowed to take outdoor exercise in winter. The American winters are so cold that bee-keepers there have found it is advantageous to winter their bees in cellars of dwelling houses or in dark thick-walled houses built for that purpose. The practice of confining bees to their hives and wintering them in dwelling houses has never, to my knowledge, been fairly and extensively tried in this country. Sometimes my father wintered weak hives indoors, and occasionally I have done it successfully. Strong colonies well covered are able to withstand and come through the severest of English winters.

The watchword of earnest apiarians seeking great results will be, for a few years, "Strong hives in autumn," and if they follow

his they will become successful men, and know that with strong populous stocks in autumn the dangers and losses of winter life will be neither feared nor felt.—A. PETTIGREW.

NOTES ON BEES IN THE NORTH OF IRELAND.

LEST the readers of this Journal should think that good taste and industry have left our country, I venture at the end of the season to describe my experience with our bees in 1879-1880. It has been stated so often in this Journal that 1879 was disastrous amongst bees that I need hardly endorse it as regards Ireland. Rain and wind prevailed all the honey season here; but for three or four seasons it has been so unpropitious for honey gathering that nearly all the old apiarians have been discouraged.

Still this may have good results, as they who will keep bees for pleasure or profit must adopt another system. Thanks to this Journal this new principle I have been following for three or four seasons back with great satisfaction; for, terrible as 1879 was, I had one stock that sent off three casts and another two while my neighbours had none—not surprising with their straw skeps and trough of dry sugar all winter. But best of all, under the modern plan I drove a hive into a straw skep containing a few empty combs in September 1879. This season the bees made a splendid stock, and although not at all numerous this spring they very soon filled the skep to the bottom, and also a very large glass super, which I took from them in September, drove the bees, and obtained all the honey. I united them with a prosperous stock in a Woodbury hive, which is now very strong. I fed the former abundantly in autumn, winter, and spring, with syrup made from 4 lbs. of loaf sugar to a quart of water, one spoonful of vinegar, and half a glass of best whisky. This mixture I gave them in dishfuls of 2 or 3 lbs. well covered with small pieces of sticks. I can now perform the operations of driving, uniting, and transferring—all, I may say, through your instructions and with perseverance. As I have more to say on this subject I will reserve it for another communication.—COMBER, *Co. Down*.

CONGRESS OF GERMAN AND AUSTRIAN BEE-KEEPERS.

HAVING attended the late meeting convened by German bee-masters, and taken some part in it as an exhibitor and winner of a State prize medal, I thought some account of the apiarian appliances there exhibited and of the proceedings generally might be acceptable to your readers. This year was the twenty-fifth anniversary of these meetings, and therefore a time of unusual interest.

The city of Cologne was well chosen for the Congress. It is convenient of access from all parts of Germany and elsewhere, and possesses many attractions. Every hospitality was shown the apiarians; all public places were freely thrown open to our inspection. The place selected for the meeting was the Victoria Hall, in the Waidmarkt, which was indicated by a number of flags and banners with appropriate signs of bee industry, announcing that the "Wandering Society of Bee-keepers" were holding their annual Exhibition within.

At eleven o'clock on the opening day the Burgomaster, Dr. Becker, opened the Exhibition in the large hall with a short address to the Executive Committee, in which he expressed the hope that the present Exhibition, together with the interesting papers to be discussed, would prove a special means of advancing apiculture in the sister provinces of Rhineland and Westphalia. Many of the most prominent guests were already present—viz., Dr. Dzierzon, Professor Keller of Milan, Mr. Gatter, Editor of a Vienna paper, and others. These were formally introduced and cordially welcomed. Dr. Dzierzon's entry was announced by a few strains of appropriate music. After the opening ceremony, which occupied little more than a quarter of an hour, the Committee and guests went into the smaller hall adjoining to view the Exhibition.

The exhibits had not all arrived, but there were sufficient to show that the whole affair would be a great success both as regards the quantity and quality of the objects already placed. A well-arranged catalogue of fifty-two pages with entries from 165 exhibitors was of great assistance. Throughout the next day arrivals of objects were frequent, so that the spaces appropriated were filled almost to overflowing. The hives with living bees were located in a garden adjoining the Exhibition hall. In the evening of this day the number of the more prominent guests was greatly added to. Among these arrivals were Mr. Vogel, Count Pfest, and others. It was a novel sight to an Englishman to witness these bee-fathers meet; they seemed so delighted to see each other, and cordially embraced, thus practically carrying out the Scripture injunction, "Salute one another with an holy kiss." In a future issue I will give a description of some of the more prominent exhibits.—ALFRED NEIGHBOUR.

OUR LETTER BOX.

Book (*Ramulho*).—The "Pigeon Book" by B. P. Brent, published at this

office, price 1s. 7d. post free, is precisely what you require. The fourth edition is in the press, and will be ready in a few weeks.

Poultry Shows (*Expert*).—We are obliged by your offer, but our intention is only to publish reports of a few shows that are of wide and general importance, as our space will be more usefully occupied with practical matter that will be of greater service to the majority of our readers.

Salt for Dairy Cows (*C. J. A.*).—Salt should never be mixed with the food of dairy cows, as too much may be given; they should always have access to rock salt in lumps, and will then never injure themselves. It is not advisable to mix salt with inferior or damaged hay when cut into chaff, but it will pay well to use the flavouring spice sold by Bowick & Co. of Bedford. It should be mixed with the chaff for twenty-four hours before feeding time. Swedes when pitted in the field in small conical heaps will keep well covered with earth only, but they should be cast together with roots attached and the greens twisted off by hand. No knife should ever be allowed to touch the roots or stems. They will then keep well without any ventilation, as often required in large store heaps of roots.

Horse Drills and Ploughs (*Hodge*).—One-horse drills for both Turnip seed and corn may be obtained of nearly all the best and largest implement makers in the kingdom, but some of them are made too wide and heavy for one horse when manure is drilled with the seed and corn, particularly upon hilly land. No one-horse drill should be wider than 3 feet 6 inches between the wheels. Makers' names—Messrs. Reeves & Son, Westbury, Wilts; and Tasker & Son, Waterloo Works, near Andover, Hants. One-horse ploughs will not answer upon stiff loamy soils, except in summer tillage where the land has been previously moved and worked. Upon light, dry, friable land we have employed them for thirty years past; but since the double-furrow ploughs have been introduced we prefer them, because one man can direct the two horses, whereas two single ploughs to do the same work require two men. There has been no special trial of one-horse ploughs for some years past at the Royal Meetings. Howards of Bedford make excellent one-horse ploughs.

METEOROLOGICAL OBSERVATIONS.

CAMDEN SQUARE, LONDON.

Lat. 51° 32' 40" N.; Long. 0° 8' 0" W.; Altitude, 111 feet.

DATE.		9 A.M.					IN THE DAY.					Rain.
1880. Dec.		Baromet- er at 32° at Sea and Level	Hygrome- ter.		Direction of Wind.	Temp. of Soil at 1 foot.	Shade Tem- perature.		Radiation Temperature.

REMARKS.

12th.—Very fine with bright sunshine all day; clear moonlight evening.
13th.—Overcast and dull, rather windy.
14th.—Very damp overcast day, rain at intervals; finer in evening—moonlight.
15th.—Slight fog and drizzle early part of morning, rain heavier from 9 A.M. till 6 P.M.; fine evening and moonlight.
16th.—Rain until evening, then fine and cold; dark for a short time at 1 P.M.
17th.—Fine but overcast and cold, few flakes of snow at 10 A.M.; snow at 9 P.M.
18th.—Morning fine with few gleams of sunshine; rain commenced at 1.45 P.M. and continued slightly for several hours; moonlight night.

A damp uncomfortable week, although the temperature remains above the average.—G. J. SYMONS.

COVENT GARDEN MARKET.—DECEMBER 22.

OUR Market is well supplied with all ordinary goods, and although this is Christmas week trade is anything but brisk.

STOCK-TAKING.

ONE of the most universal of customs, and one of the best—indeed one that is essential to the conduct of business and the welfare of families, consists in what is known as “stock-taking”—a winding-up of accounts, tracing at the same time the causes of failures, if any, and noting the elements that have contributed to success.

There are few people, however humble their circumstances, who do not in some rude way take a retrospective glance over a closing year, and compare their present position with their circumstances of twelve months previously. Others are more precise; they not only make a general comparison of their position now and then, but, by a careful system of recording events and the circumstances affecting them, they can trace a failure to its source and better understand what has been the root of an achieved success than could possibly be done by trusting to memory alone.

In all well-conducted trade establishments the everyday events are recorded with accuracy and punctuality, and at the close of the year the exact position of the business, its progress or decline, its profit and loss, can be determined, together with the contributory causes that have produced the results. The tracing of failures to their sources is one of the most important exercises a man can engage in. Dwelling on success is pleasant, and mankind are prone to indulge in that practice—to rest in the thought of what has been accomplished instead of devoting the mind to what has yet to be achieved.

Stock-taking on a systematic principle is regarded by a vast number of people as necessary in large trades, but in the small concerns of every man's life it is not thought to be of consequence. Nothing can be more erroneous than such an idea. No useful work in which a man is engaged can be too trivial for notice; its nature, the objects sought, the means employed, and the results attained should be recorded, and information of the most practical value and lasting worth will be obtained. This applies to workers in every vocation, and to none more forcibly than those engaged in the cultivation of the soil—horticulture and agriculture. “The worth of a State in the long run is the worth of the individuals composing it,” is a great truth which should be indelibly impressed on the mind of every man who reads these pages; and the remark may be properly and specially applied to the world of horticulture. Its character, usefulness, and advancement depends on the work of every man engaged in it—on the soundness, thoroughness, and accuracy of that work. Societies may, and indeed have, done much good, and the teachings of the

press have been of inestimable value; but, after all, honest and excellent work, which meets in the most satisfactory manner the requirements of families at home, is the best teacher, and is more effectual, more useful, and more advantageous, regarded in a broad aspect, than that devoted to the glitter of shows. If showing is the chief object of the owner of a garden, it is the duty of a gardener to carry out that object assiduously and perseveringly, and he will at the same time give private satisfaction—which is essentially in that case a “home requirement”—and gain public appreciation. But, on the other hand, if showing is the object of a gardener only, the employer giving no encouragement to the practice, then a mistake is made if the former persists in riding his hobby horse, which will sooner or later throw him in the dust. Gardening, then, which from the employer's point of view has been abused, is no longer indulged in, the owner applying his wealth to other purposes. By this cause alone—devoting the resources of an employer towards an object that has not his sympathy, gardening has to a very sensible extent suffered, and the means for carrying out the art in its higher aspects have in hundreds if not thousands of cases been abridged. The prosperity, therefore, of gardening emphatically depends on the character of every man individually who is engaged in it. Let every gardener, then, take stock of his position and arrive at a sound judgment as to the most judicious mode of performing his duties. Let him remember that from various causes many people are not so rich as they seem, that the profits of trade have been minimised and rents curtailed, that the luxuries of life are not so readily attainable as formerly, and he must be willing to conform to the changed circumstances until the recurrence of better times.

Further, it will be well to recognise the fact that society is every day becoming more commercialised. Old customs, good as they are, cannot be retained because they are old, and full money's worth is in everything expected for money. Many a gardener is at this moment uncomfortable because he has not the necessary means afforded him for performing his duties as he would wish; but it is certain that many employers are equally uncomfortable because they are unable to do what they desire in the various departments of their establishments.

It is unfortunately too true that not a few able, industrious, conscientious gardeners have difficulties almost unbearable to contend with; they may, however, well consider that, hard as they feel their lot to be, there are many still more unfortunate than themselves—hundreds of them, who would rush to fill a vacancy if created. A gardener's life is very much of a lottery regarded from one point of view. With friends and fortune and “luck,” a man finds himself in a good position early in life, while others wait or wander for years before their turns come. Still, the true course is to plod on trustfully, hopefully; a man may wait too long and wander too far—like an able gardener of the north, who waited for a “great place” until his savings were nearly exhausted, then went to London to seek friends and found himself in a garret near one of the great railway termini, and was glad to “do anything” to raise his rent of 6s. a week and find bread for his wife and six children. This is an “owre true tale,” and there are numbers of men who have waited and wandered until they could wait no longer nor wander farther, and have had to leave the ranks of their craft.

It is not to be expected that those who have been so

unfortunate will accept the truth of Dr. Johnson's observation, that "all the complaints which are made of the world are unjust. I never knew a man of merit neglected. It was generally by his own fault that he failed of success." Yet assuredly those words contain much force, and should be pondered over until the full significance of the remark is appreciated by all young men.

The pith of the above sentence is contained in the word "merit," and its right interpretation. It is not what a man thinks of himself, but what others think of him, by which a true estimate of his character is formed. Work that a smart young gardener might deem degrading, his employer might regard the cheerful performance of as a most meritorious act. It is much to be feared that there are a few young men left who would feel themselves subjected to a great indignity if requested to leave "the houses" for an hour or two and assist in digging a plot of ground. But what would they think of a young gardener earning £30 by washing a carriage, and attracting the favourable notice of a duke by shaking a carpet? Some years ago a young man who had received an excellent training in large gardening establishments, after waiting a year for a "big place," fortunately took a small one—a single-handed place. He determined to manage it well, and also had the good sense to assist in other work occasionally without being asked to do so, when he saw aid was needed. In the absence of the groom one day the carriage was wanted; the gentleman could harness the horse and drive, and he would have taken the dirty vehicle, but the gardener promptly intervened and washed it. The owner was so favourably impressed by the man's act that he added £10 a year to his wages. Three years afterwards a noble duke, after admiring the garden generally and some feature particularly, asked for the gardener. "There he is in the field helping to shake carpets," replied the gentleman. "Oh!" answered the duke, "if he can garden like this, and shake carpets like that, he will do for me." The man's single-handed career then ended, and his carpet-shaking too. That episode in a gardener's life was told to me by the gentleman in question, and is strictly true. Stock was taken of that young gardener as it is of all young men, and those who are the most punctual and attentive, industrious and willing, usually attain to good positions comparatively early in life.

Trusting to friends for assistance, and doing little beyond waiting for an opportunity, is not the true way to succeed. Taking stock of men, and wants, and means, and circumstances, and meeting them in the best possible way, is the true mode of promoting good will, and making the closing year pleasant and the opening year bright.—A VETERAN.

THE AUTUMN FLOWERING OF AURICULAS.

I SEE a correspondent at page 545 says the unusual quantity of autumn-blooming Auriculas does not seem to promise a good display in the spring. What is the reason that Auriculas bloom so much in autumn? I have not a large collection, and not 1 per cent. of the plants have bloomed, but then I give them abundance of water through the summer and autumn until the cold of winter stops the growth. Most spring-flowering plants and all spring-flowering Primulas have a tendency to bloom in autumn and early winter after a hot dry season; and if Auriculas have similar conditions it is only natural that they should also bloom at that time. These beautiful flowers are so easily cultivated that I should be glad to see them patronised by gardeners in the same way as Cinerarias, and made part of the usual stock of the garden. Will some florist kindly answer the above question?—R. P. B.

GALVANISED WIRE AND FRUIT TREES.

(Continued from page 569.)

A STEWARD and estate agent of great experience and ability once taught me a useful lesson. His object through life had been to gain a thorough knowledge of everything connected with his charge, including the management of land. Engaged in high-class farming he was purchasing soot largely, but had an idea that it was not wholly free from adulteration, and he was anxious to acquire a simple mode of testing the genuineness or otherwise of the article. It occurred to him that a chimney-sweep might be of service in this respect, and he determined to make friends with one—not a "master sweep," who had soot to sell—he was too

shrewd for that; but a journeyman, who had to climb up chimneys and crawl through flues, such labour then being legal. A silver coin and a compliment, ostensibly as an expression of satisfaction at the manner in which a dusky worker had performed his duty, easily led the man into a conversation which naturally glided into soot and its uses, and in reply to a question adroitly put as to how to know whether soot was pure or not, the good-humoured individual observed, "I'll tell you, sir, how you may always know. Push your hand into a heap and grasp a handful as tightly as possible. If it flies through your fingers and you can't hold it you may be certain the soot is pure; but if it cakes in your hand and you can hold it, you may be sure it is adulterated." The value of this information, obtained at the cost of half-a-crown, was estimated by the steward at £100, and his advice to others seeking knowledge was afterwards conveyed in the sentence, "If you want to know anything about soot make friends with a sweep."

"But what has this to do with galvanised wire and fruit trees?" someone will ask. It has nothing immediately to do with the subject, but the hint is worth recording; and it was the remembrance of it that led me to make some inquiries in search of a mode of reconciling the conflicting statements of several writers who could not be mistaken on the subject, that the wire in question was innocuous in some cases and decidedly injurious in others when employed in connection with fruit trees. Remembering the old steward's advice I determined to make friends—not with a sweep, but an intelligent mechanic, who had assisted in making and using hundreds of miles of galvanised wire. This man I found, and further learned that he was a lover of flowers; indeed, he has a greenhouse with a Vine in it, and I could see he felt quite proud when I went to "look at his plants."

The Vine I perceived was trained to copper wire. I asked in a casual manner why he did not use galvanised wire. He replied with an astonished look, "Do you think I'm a fool?" By way of assuring him of the contrary I told him that I had used the wire for years, and seen miles of it used for fruit trees of all kinds without injury, but that other gardeners had found it decidedly injurious. "Of course they have," was the reply; it *must* be injurious, and your wire had not been long in the acid, or it was old wire." I thought the moment now opportune to promise to give my friend a "few cuttings," and he became the more communicative. He earned the cuttings and had them, and his theory or practice is worth recording with another theory that has been suggested, and between the two a little light may possibly be thrown on an obscure subject.

The so-called galvanised wire I have found is not galvanised wire at all, it is simply iron wire drawn through a bath of molten zinc and coated. Neither electricity nor galvanism, as in the case of electro-plating, has anything to do with the process; but before the wire is placed in the zinc bath it is immersed in muriatic acid with the object of rendering the surface perfectly clean, as, if the slightest particle of grease or any extraneous matter adheres to it, it will not "take the zinc."

If the wire is coated when quite new, and free from rust, grease, or any other impurity, it has only to remain in the acid for a moment. This is the best wire, as it is the most tough and pliable, the fibre not being injured by the acid; but if some time has elapsed between the making of the wire and coating it, the surface becomes much soiled and a much longer immersion in the acid is imperative; to such an extent is this the case that occasionally the wire is quite saturated, and the fibre of the iron is destroyed; hence the brittleness of some wire, which all who have used it extensively will have experienced. Some wire, indeed, is so brittle or "rotten" that it cannot be used at all. A scientific friend informs me that the wire does not absorb the acid at all, but the workman says it does, and changes its colour throughout, as anyone can see who cuts it; he also says that all the acid absorbed by the wire "sweats" out of it again through the zinc; and further, if one end of a thick piece of galvanised iron is placed in the fire he can "see the escape of the acid through the zinc coating." Hence he concludes that the escaping acid that "works out" and comes in contact with vegetation must corrode it and destroy that portion of the branch or leaf that it touches. If this man's theory, derived wholly from practice and observation, is correct, we arrive at a reason why in some gardens the wire is injurious and in others not—namely, some of the wire employed has been saturated with the powerful acid, and other wire has only been slightly acted on by this cleansing medium; or some wire has been used when almost fresh from the bath, while another sample is older and time has been afforded for the escape of the poisonous fluid.

This accords with the remark of a correspondent, "W. W.," who has stated that there is "galvanised wire and galvanised wire," and that "the older the wire the more safe it is to use." He arrived

at this conclusion after many experiments for the purpose of selecting the best wire for the manufacture of Pea hurdles. "W. W." is undoubtedly right. Old galvanised wire is decidedly much less injurious than new, and some wire is almost certainly innocuous. This I have proved by experiment this summer, and I have seen the same result on a large scale in a garden in Surrey. A short wall was covered with two or three old Peach trees secured to galvanised wire; a year or two ago the wall was lengthened considerably, young trees planted and new wire used; this new wire injured the growths that touched it, while the growths attached to the old wire on the old portion of the wall were not affected in any way. This is a clear demonstration of the difference between some old and some new wire. On this aspect of the question it may perhaps be useful to record that my intelligent artisan friend states, that if new wire must be used it ought to be placed in water for a few days, and it will be much less liable to do injury to Vines or trees. The accuracy of this statement I have not proved, yet the man's idea is not an unreasonable one; but I have proved that wire two years old and partially oxidised has scarcely left a mark on the Vine shoots that were carefully tied to it, while new wire has corroded them deeply.

The question of tight or careless tying is wholly out of court in the case under notice, as the utmost care was taken and special means adopted guarding against this contingency or abrasion; in fact, all the shoots were tied alike and examined daily. For a number of years I attributed the injury that I read about to the above cause, as I had none myself where this wire was used. I am forced, then, against my previous convictions that the so-called galvanised wire is injurious under certain conditions, and I am convinced that the writers who have adduced testimony to that effect have not been mistaken.

Although I think the evidence of an intelligent flower-loving, wire-making artisan worthy of publication in connection with this subject, and while I think there may possibly be some grounds for the views he entertains, I do not consider that the absorption by the iron of the acid and its subsequent release satisfactorily accounts in all cases for the injury that has been done by the use of the wire. I have rendered his ideas as clearly as possible. They are, at the least, not illogical, and they open up a fresh line of thought in the consideration of a subject of a very debateable nature.

I will pursue the question further, for although it is admittedly difficult, yet it is of considerable importance to all who are engaged in the cultivation of plants and fruit.—J. WRIGHT.

(To be continued)

ECKLINVILLE SEEDLING APPLE.

MR. WITHERSPOON, on page 549, asks for information respecting the history of this Apple. If your correspondent refers to the last edition of the "Fruit Manual," he will find on page 49 the following note:—"The tree was raised at Ecklinville, four miles from Portaferry, and eighteen from Belfast, by a Scotch gardener of the name of Logan, more than half a century ago, and it is now extensively grown in Ireland and the south of Scotland." It has possibly spread from Scotland into Durham, and Mr. Witherspoon appears to have a quick eye for what is good, hence his approval of the excellent and very useful Apple. It is a market variety of the first order, as the trees come into bearing quickly and bear abundance of fruit of good appearance and quality. It may be grown successfully in the form of bushes on the Paradise stock, which is, perhaps, the best plan, or as standards on the Crab. It is a valuable and profitable variety, and should be freely planted.—A MARKET GROWER.

THE HORTICULTURAL ASPECT OF 1880.

THERE are various ways in which we may look back on the year that is now closing around us. The thoughtful cannot regard the lapse of time without serious reflection as to the way in which it has been used or abused. The merchant, the politician, the student all have their way of taking stock of the past and of forming their plans for the future. Why not, then, the horticulturist? and by that term I would imply all who love and take interest in a garden, regardless of whether their love is a scientific one or not. In fact I am inclined to think that they who have less of science in their horticulture have more of love for it. They work and plod on in their own quiet way, and get perhaps more enjoyment out of their garden than does the man who knows all theories and understands all the arcana of science; and it is well that it is so, for the latter are few, while the former are a mighty multitude. As one, then, who has a real love for a garden, and has, moreover, opportunities of seeing and hearing much concern-

ing horticulture, I would give a cursory view of the past year in a horticultural point of view.

We can hardly write of a year's horticulture without thinking of the Royal Horticultural Society; and I am sure everybody must admire the pluck and energy with which it holds on its way despite of all the difficulties it has to contend with. The incubus of the debenture-holders and the threatened action of the Law Courts have no power to make their able Secretary less cheery or their Council less confident. I remember some years ago when its affairs were at its worst, and "our Doctor" boldly essayed its secretaryship, I compared him to Curtius leaping into the gulf of the Forum. The comparison does not, however, hold good, for the gulf finished Curtius but the secretaryship has not finished the Doctor, but has rather given him a new lease. Happily now the unseemly squabbles that once disfigured it, the "cliqueism" which was rampant, and the many pitfalls that surrounded it on all sides, have vanished. It is probable some of these days that it will get rid of a portion of the white elephant, leaving only the tusks for itself—i.e., a large portion of the garden, which is indeed the delight of nurserymaids, but, as far as one can see, of no other earthly use, may be sold and the Society set free. It is gratifying to see how the confidence of the horticultural public is steadily given to it. Is a new flower, fruit, or vegetable raised, it finds its way there; and then how loyal, amidst much to discourage them, have the great metropolitan and suburban nurserymen been! One thing is, I think, however, to be deplored—the Society is Royal only in name: rarely do any of the members of the Royal Family visit its exhibitions and cheer its hard-working Council with their aid. I do not stop to compare this with the manner in which the members of foreign Royal Families support their horticultural shows. But almost anything else in our own country seems to enjoy the sunshine of Royal favour. Races, regattas, agricultural exhibitions, American midgetts, &c., all these are patronised, but not the Royal Horticultural Society. It is too much to hope that this may be bettered in the future. Of course horticulture ought to support its Society without this favour, but still a breath of encouragement from these high latitudes has an invigorating effect.

A considerable change has come over the fashion of gardening which has received a great impetus during the last year, I mean the decline of the bedding-out system. In every direction I have seen beds turfed over, and lamentations over the time and money that the bedding-out system wastes; but I think a word of warning on this point is necessary. We are a people of extremes. The swing of the pendulum is wide, and when it has gone to the utmost limit in one direction it is apt to go off to the other. Some few years ago maidens and matrons enveloped themselves in hideous crinolines, so that we poor mortals had a difficulty in finding sitting room in a railway carriage or in a pew in church; now they swathe themselves so tightly that they have the difficulty in sitting, not we. The dear creatures wore what they called bonnets, but it was hard to believe they had anything on their heads; now they are gradually coming back to the old poke, in the deep recesses of which they hide their faces. And so it is in gardening. The bedding-out system invaded every place. The nobleman and the squire set the example, and then parsons in their country vicarages, citizens in their suburban retreats, farmers, doctors, all went in for it. Lawns were destroyed, small front gardens were made to look ridiculous, and even the cottager in our quiet country villages rooted out his Primroses, Aconites, and Lilies in order that he might, like his neighbours, have a few Mrs. Pollock or yellow Calceolarias. Now this is all altering, and one great ally has come in to help in the change—lawn tennis. Everybody must have this. Like the boys with their tops and hoops, children of a larger growth are so delighted with their new toy that they must have some place to play it in. Hence the lawn has resumed its place, and to some extent the herbaceous border has been introduced. But, as I have said, we are in danger of rushing into extremes. For our large places and for public gardens nothing can be better adapted than the bedding-out system. The Luxembourg at Paris is the only public place where I have seen the mixed border used, and it is the least effective for display of all their public parks; but if kept within due bounds I am sure most people will rejoice at the change, gardeners most of all. I think carpet bedding and lawn tennis have together given the *coup de grâce* to the system.

Horticulture is, if we may judge from the many signs we see, widening its area, and the more it does so the better for our people. I am not quite sure whether amongst our great people there is not a diminution in its interest. We have seen several large collections of Orchids and other plants dispersed during the past year, while the "return for my money" principle seems to be extending. 'I am very sorry I cannot go round the houses

with you, for I am just preparing to send off to market, and this is the second time to-day," was the remark of the gardener of one of our wealthiest noblemen. "I am ashamed to go round the garden with you. You recollect what it was; now I have not half the labour allowed me that I used to have, and in consequence the garden is no pleasure to me. Weeds and untidiness characterise it, but the squire says he cannot afford it," was addressed to myself in visiting one of the most famous gardens in the kingdom for its fruit and vegetable produce; while I think, on the other hand, many more persons of smaller ambition are engaging in it. Let me here quote a letter I have just received from one I have never seen. "The letters of yourself and others in the *Journal of Horticulture* are eagerly watched for and read by us in the north, and I can assure you that to these letters is due in no small degree the increasing demand for Roses in my own particular district. In fact it is no uncommon thing to find cottagers with a hundred plants and longing for more, tending them with every attention that our smoky climate requires. I know men, who beforetime were drunken and bad characters, spend their time in the garden instead of the public house; these men have become decent members of society instead of so many pigs." I, who have an opportunity of being at the Manchester and London shows, am constantly asked my opinion on such and such Roses, and on my saying they are good but costly am met by the reply, "I don't care for the cost if only they are first-rate." This is encouraging, I think, to us, and ought to make us very careful as to what we recommend. Before I leave this branch of my subject I may, I hope, with pardonable egotism, refer to the continued success of the Horticultural Club. More than double the number of members have been elected in 1880 as compared with 1879; and although changes are continually taking place, yet the total number of members continues steady. As we have often been met with the assertion that a year or two would see its exit, it is gratifying to find that after six years of existence it is still flourishing, and affords a pleasant meeting place for many who are interested in horticulture.

I do not think that the past year has been distinguished for any startling novelties, either as introductions from abroad or the results of hybridisation at home. I have before me the list of all those plants and flowers which have been certificated by the Floral Committee, and while many are interesting there is nothing very remarkable to note. Some good Lilies have been shown from Japan and elsewhere; new florists' flowers have not been very numerous, but amongst them have been some valuable additions, but they are but just a little in advance of those we already possess. We have not yet a blue Dahlia or a pure white or deep yellow Hybrid Perpetual Rose. As usual too many characters have been damaged (I mean of flowers, not of men), and things once highly thought of have been consigned to the rubbish heap.

Such is a brief bird's-eye view from my own standpoint of horticulture in 1880. Our season, though not a favourable one, was better than last year. The winter as yet has not set in with severity, and we can only hope that we may look forward with brighter prospects to 1881.—D., Deal.

AN HOUR AT CHELSEA.

HAVING had a rapid "run round" Messrs. Veitch's establishment during Christmas week, the following notes may not be without interest to many of your readers:—In the nursery some improvements have recently been made. The long entrance corridor has been thoroughly renovated, the old Lapagerias having been removed and young plants inserted. Tree Ferns, Palms, Euryas, and various other plants ornamental by their foliage or berries are tastefully arranged, and the corridor has seldom if ever looked better than it does now.

In each of the hundred houses and pits there is something of merit, fresh healthy stocks of old and popular plants, or batches more or less large of others new and rare. Flowers, too, are plentiful. In one house *Azalea narcissiflora* and some others, *Sparmannias*, *Begonia insignis*, *Linum trigynum*, and similarly useful plants for midwinter decoration are in quantity; in another the display of *Erica hyemalis* shows in the most convincing manner how valuable, even indispensable, this *Erica* is for rendering cool structures attractive at this season. The plants are splendidly grown, many of them, though only in small 48-size pots, being more than a foot in diameter with twelve to eighteen principal growths or "horns" densely laden with delicate flowers, the subsidiary growths being equally well flowered quite down to the pots. These plants are masses of chaste beauty, and cannot fail to be admired by all who see them. In the same house some fine clumps of Christmas Roses (*Helleborus niger maximus*) are as effective as *Eucharises*, each plant producing upwards of fifty flowers and

buds. Primulas, Tree Carnations, Cyclamens, Lily of the Valley, each have structures devoted to them; while in the stoves the brilliant colours of the Crotons—the new forms Hawkeri and Cronstadti being very striking—the great display of *Nepenthes*, the dark red pitchers of *N. bicalcarata* being conspicuous, contribute to the varied character of the display.

The extensive collections of Orchids comprise a very large number of species and varieties, and the general condition of the plants is excellent. This is by no means the best time of year for a display of Orchids, yet many were in flower, and a still greater number will soon be in full beauty. The handsome and peculiar *Angraecum sesquipedale* is represented, several extremely fine specimens are bearing eight flowers of unusual size. *Barkeria Lindleyana* is especially noteworthy for its elegant racemes of rich rosy purple flowers, one variety being very distinct both in size and colour of the blooms. The lovely *Laelia anceps* is highly attractive; the colour of the labellum on one specimen is remarkably rich, and indicates a variety of considerable value. Among the *Odontoglossums* it is only necessary to mention the names of such well-known forms as *O. Alexandrae*, *O. Roezlii*, and *O. Andersonianum*, all in fine condition, and to these may be added the charming new *O. blandum*, a pretty dwarf species recently certificated at Kensington, and *O. anceps*, very striking, also accorded a similar honour at the same time. *Calanthes* have produced a grand display, but are now past their best, though sufficient are still left to show what most gardeners now well know—namely, the surprising utility of the plants for decoration in winter. The beautiful hybrid *Dendrobium endocharis*, noted

Fig. 105.—High Cross Hybrid.

last week in the *Journal*, is flowering well; a compact specimen with several growths has a large number of its fragrant blooms. The brilliant *Sophronis grandiflora* and its rare but pretty relative *S. violacea* are attractive, while *Saccolabium giganteum*, *S. violaceum*, *Laelia Dayana*, *Oncidium Forbesii*, *O. cheiroporum*, *Lycaste alba*, *Chysis Chelsoni*, *Comparettia falcata*, and many others, are admirable. Among the prospective attractions are the *Phalaenopses*, of which there will be, if the weather proves favourable, an extraordinarily grand display. In one house and on small plants there are about 450 spikes, forming, as my conductor not inaptly termed it, "a network of stems." A very large imported stock of *Cypripedium Lowi* is in superb health, the plants growing most vigorously. Altogether the Orchid houses well repay for a visit, as indeed they do at any period of the year where so many plants are so carefully grown.

The seed department is an important feature of the nursery; and the great structural additions that have been completed render it a matter of surprise, seeing the crowded state of men and goods, how the work of this department could have been previously conducted. The bulbs are nearly all cleared out (it has been an excellent "bulb season"), and it is only by working far into the night as well as by day that the seed orders can be executed with that promptitude that is requisite for the smooth and satisfactory dispatch of business. Those who only advocate the culture of "good old things" would be surprised at the great demand for seed of "novelties" of promise and "specialities" of proved worth. The new Melon High Cross Hybrid, now being distributed by the firm, may be referred to, as it is the only one of the three varieties that were certificated this year that has not been figured in your *Journal*. The reduced engraving, fig. 105, will show the handsome

form, the densely netted character, and the deep flesh of this variety; while if it had not been of superior quality it would not have received the honour that was awarded to it when six fruits were exhibited at the summer Show of the Royal Botanic Society by its raiser, Mr. J. Hopkins, gardener to R. Thornton, Esq., High Cross, Framfield.

The visitor cannot fail to notice the excellent order that prevails in every branch, and the brisk business-like air that pervades the establishment.—A GARDENER.

CULTURE OF LILIUM LANCIFOLIUM (SPECIOSUM).

I CAN well remember, over thirty years ago, *Lilium lancifolium* and the variety *album* being grown in pots 14 and 16 inches in diameter, also ten or twelve bulbs together being planted in a peat border in the conservatory, and I can quite understand the pleasure it gave "N. I. D." to see the fine specimens he mentions at page 523 as growing in the garden of Sir Humphrey de Trafford.

My mode of culture, which I have followed over twenty years with success, is as follows:—When the plants have flowered I have the pots placed upon a south border, so that the bulbs may have the full benefit of the sun to ripen them. When the stems are quite yellow they are cut down, and the pots are laid upon their sides to prevent the bulbs becoming too wet. In November they are taken to the potting shed, where they are shaken out—each variety is kept separate—the pots are then washed and employed again when dry.

The compost I employ for potting consists of one-half of turfy loam about an inch thick broken into pieces the size of an egg, and the other half turfy peat in large pieces, decayed stable manure, leaf soil, pieces of sandstone and charcoal, with a sprinkling of white coarse sand, and a small proportion of soot, all well mixed. Where there are a number of pots required those 12 inches in diameter are most convenient, and 8-inch pots are very useful. Great care must be taken to secure good drainage. If the plants become waterlogged all efforts to obtain a good specimen will be in vain. After the pots are crocked I place pieces of turf over the drainage. I then rather more than half fill the pots with the compost, press it down to prevent its sinking too much, and place the bulbs on the soil near each other. I cover the bulbs with 1½ inch depth of the compost, and a dusting of white sand over the top. The pots are then placed in a vinery where there is ventilation day and night in mild weather, and no fire after the first week in December, where they remain until the first week in April. No water is given them in winter; and as in April the vinery is closed and too warm for them, they are arranged on a south border outside close together, sheltered from the east wind and covered with a mat on frosty nights. When frost is past the Lilies are placed upon a north border, where they remain until the flowers commence opening and are then removed to the conservatory. A top-dressing of loam and decayed dung is applied to the soil. They are secured to stakes, and at every alternate watering they are supplied with liquid manure. They require abundance of water while they are growing, and with good drainage and open compost the water passes away quickly. By the above method I have been able to grow dwarf robust plants with abundance of flowers and dark green healthy leaves.—JOHN NUNNS, *Wimbledon*.

STRAWBERRY FARMING IN SCOTLAND.

It may not be generally known that in certain districts of Scotland the cultivation of the Strawberry has of late years assumed considerable proportions. There is a steady demand for jam made of this delicious fruit, and consequently wholesale confectioners are consuming increasing quantities, some of them to the extent of hundreds of tons annually. There is, besides, a steady and apparently unlimited demand for the fresh fruit for table use, and thus the industry has grown during the last twenty years to an enormous extent. The principal centres of Strawberry farming are Blairgowrie, Aberdeen, and Perth. I am not aware what acreage may be cultivated in the latter two districts, but I have taken some statistics that show that within two miles of where I now write there are upwards of 200 acres under Strawberry cultivation; and as 2 tons per acre is considered a fair average return, it will be seen that the quantity of fruit yearly marketed from this district is very considerable.

The great bulk of the crop is sent off to the confectioners in barrels holding from 1 to 2 cwt. each, and last season fetched from £28 to £30 per ton. Those who, like myself, were at the extra trouble and expense of packing the fruit for table use realised on an average a third more than the above prices.

Most of the growers are men who make a speciality of the crop,

though not a few farmers cultivate a few acres along with their other crops. The Strawberry farms proper are nearly all on land recently reclaimed from the moor. In its natural state this land, covered as it is by Broom and Heather, is not worth 5s. an acre, and even when reclaimed is not worth over 15s. for agricultural purposes; yet the usual rent, in the form of a perpetual feu, is £5 per acre yearly. In addition to this heavy annual burden the feuar must expend say £20 per acre in trenching and laying down a preparatory crop, erect his own house and fences, and make roads. Thus heavily handicapped it may seem surprising that he can live and bring up a family on from four to six acres; yet so kindly is the soil that by the exercise of due industry there are comparatively few who fail.

The soil in its natural state is nothing more than a thin layer of turf, 6 or 8 inches deep, resting on a deep bed of rusty gravel. In trenching a spit of gravel is brought to the surface, thus increasing the cultivated depth to from 12 to 14 inches. Such is the apparently unpromising land to work upon, yet there seems to be something in it that makes it congenial to the Strawberry plant, and in fact insures with less than ordinary trouble and expense a yearly return that contrasts favourably with the best results from rich and highly cultivated districts. In fact the nature of the soil and of the methods here practised are in direct contradiction to generally received theories. I could conceive a stranger who knew nothing but what he might have learned here maintaining that the Strawberry plant required only a poor soil, no bottom moisture, little or no manure, and only a moderate amount of labour. Be that as it may, I do think that the generally received opinions on Strawberry culture require some amount of overhauling. As to the soil, our experience has certainly proved that land quite unfit for ordinary farm rotation can grow Strawberries, in quantity a fair average, and in quality acknowledged superior. As to moisture, no water is found in our gravel at a less depth than 28 to 30 feet, and the rainfall is one of the lowest in Britain, yet even the late exceptionally dry summer gave us a fair average crop. Those who maintain water to be the first, second, and third requisite to successful Strawberry culture may ponder over my facts, explain them as they may. As to manure, the rule here is to prepare the ground for the Turnips. The plants are put in on the drills, and there they are left without further manure till five or six crops have been gathered. I do not say this is either the best plan or a general one, but it is quite common; yet experts direct us to trench in at least 20 tons of manure per acre before planting, and then mulch heavily each succeeding year. And as to labour, while the native weeds and grasses are no doubt troublesome to keep under if not thoroughly eradicated under the preparatory crop, I fancy that our Strawberries require not more than half that usually considered necessary. Such is the nature of our soil that, except during the first and to a small extent the second season, the plants throw out scarcely any runners, and are thus more easily cleaned.

Of course I do not mean to argue that in any poor soil and with little attention to scientific principles good results may be obtained; for even here the intelligent and progressive growers have by far the best of it. In future notes I shall indicate the principles and practice that are found to answer best in the cultivation of Strawberries on a large scale, in the hope that they may be found suitable for other localities as well.—WILLIAM RAITT, *Blairgowrie*.

(To be continued.)

CARNATIONS AT CHRISTMAS.

FEW flowers are more welcome than these at this season of the year. They compare favourably with Roses and Lilies, and for certain purposes are more acceptable than Camellias. Carnations are emphatically flowers for cutting, and attempting to grow them as specimen plants generally results in disappointment. To have large trained plants they must be old, and these never produce flowers so freely and so fine as young plants. The plants must be grown generously throughout their career; there must be no resting to induce free flowering, nor no check at any time. When the plants are large enough they will flower, and the more healthy they are the finer the flowers will be.

They succeed best in a mixture of turfy loam three parts, the other leaf soil and decayed hotbed manure, with sufficient silver sand to render the whole open and porous. A little bone meal is a valuable addition to the soil for Carnations.

The best mode of propagating the Carnation is by cuttings; the small side shoots taken off with a heel will strike freely. These should be dibbled rather thickly in 6-inch pots about three parts filled with soil, over which a good surfacing of silver sand has been placed. After inserting the cuttings give a gentle watering with a fine rose can to settle the surface, and cover with a small

square of glass, and this should be slightly elevated to allow of the condensed water to escape; resting on the labels is sufficient. Place the pots in a temperature of 55° to 60°, and if plunged in a gentle bottom heat the cuttings will strike more readily. This, however, is not absolutely necessary, for they will strike freely in the heat named, only they take a little longer in making robust plants. The best time of the year for striking them is in the early spring months, from the first week in February to the end of April, and securing a succession of plants at different times prolongs the blooming period similarly. As soon as the young plants commence growing remove the glass for a few days and pot them off singly in 60-size pots, returning them to the same house until fresh roots are formed on the plants, after which they succeed best in a cold frame until the nights are warm enough to allow them to be arranged out of doors, which is generally from the middle to the end of May. On all favourable occasions while sheltering the plants in a cold frame draw off the lights to keep the plants as robust and short-jointed as possible.

After the plants have well rooted in their new soil and have grown from 8 to 9 inches in height pinch out the point of the leading shoot; this will cause three or four breaks, which, as they advance in growth, should be secured to neat sticks. This is all the training that is required for ordinary purposes. Some varieties are apt to grow lanky, but nevertheless bloom freely, and they can be trained to a very large size and kept in good health for three or four years. Mr. Blackley of Leyton exhibited a plant of *La Belle* in 1871 trained on a balloon trellis nearly 5 feet in height and several feet in circumference, but as a general rule it has been found that the finest flowers are produced from the younger or one-year-old plants, and the plants mostly bloom in the second year more profusely than the first. After they are about three years of age they are not so satisfactory as younger plants, hence the necessity for annual propagation. The robust varieties may be shifted into 8-inch pots, so that they may not be allowed to suffer by becoming rootbound. When the plants are placed out of doors during the hot summer months a good syringing twice a day will be highly beneficial to them in keeping red spider in check. By no means must they be allowed to suffer at the roots through insufficient supplies of water, or the lower leaves will turn yellow and the health of the plant will be impaired. Fumigate to keep green fly in check. By constant attention to these details a very useful batch of plants may be secured. They should be placed in a cool greenhouse early in October, giving them plenty of air and keeping the atmosphere tolerably dry, and they will flower throughout the winter. The following varieties are all good:—

La Belle (Blackley).—Flowers pure white, perfectly double, and delightfully fragrant; very free bloomer.

Miss Joliffe (Masters).—Pale pink or flesh colour; very fragrant and fine.

Sir Garnet Wolseley.—Buff ground, large flowers, striped, and edged with bright red; a very distinct and useful variety.

Souvenir de Malmaison.—Very large flowers, rosy flesh, and very fragrant, but blooming earlier in the season.

A. Alegatière (Alegatière).—Bright scarlet medium-size flowers; robust habit, dwarf and free flowering.

Celestial (Turner).—Rose edge; very free and distinct.

King of the Belgians (Turner).—Beautiful deep rose colour; fine large flower, but not as free a grower as some.

Guelder Rose (Turner).—Pure white, beautifully fringed; very free.

Rose Perfection (Turner).—Rose; very fine; bright and smooth.

Duke of Wellington, Gloire de Lyon, and Scarlet Defiance are a trio of fine scarlet varieties.

There are numerous other varieties in cultivation, of which mention may be made of Princess Christian, Princess Beatrice, Marchioness of Westminster, Favourite, White Swan, Prosperpine, and Rosy Morn, all raised by Mr. Turner of Slough, and may be added to a large collection if required.—A FLORIST.

SELECT VEGETABLES.

THE time is again at hand when all who grow vegetables will be called upon to select the varieties which they intend cultivating in 1881. To those who only know the names in the seed lists it may appear that any or all might be ordered and grown with equally good results; but such is not the case, as anyone who grows a great variety of vegetables soon ascertains that some which may be highly praised in the seed list are comparatively worthless, while others that are not so highly recommended are excellent. Those with means to grow many vegetables on trial will soon prove this to be correct, but others less favourably situated may spend much money and time and have inferior

crops before a proper selection can be made. To avoid this a trustworthy selection may be acceptable to many, and the following have been selected after repeated trials. Where only one of each kind is wanted the first named should be taken, but the list is as short and select as possible, and for convenience I will proceed in alphabetical order:—*Asparagus*.—Giant. *Artichokes*.—Globe, Green, Jerusalem. *Broad Beans*.—Early Improved Longford, Main Crop, Carter's Leviathan. *Dwarf Kidney Beans*.—Canadian Wonder, Osborn's Foreign, Carter's White Advancer. *Runner Beans*.—Suttons' Giant White. *Beet*.—Dell's Crimson. *Brussels Sprouts*.—Suttons' Matchless, Dalkeith Improved. *Broccoli*.—First, Veitch's Self-protecting Autumn; second, Osborn's Winter White; third, Cooling's Matchless; Fourth, Carter's Summer; fifth, Suttons' Queen. *Cucumber* (house and frame).—Telegraph (ridge), King of the Ridge. *Cauliflower*.—Carter's Extra Early, Veitch's Autumn Giant, Suttons' King of the Cauliflowers. *Cabbage*.—Carter's Early Heartwell Marrow, Main Crop, Dickson's Red Braes, Late Rosette Colewort. *Celery*.—Major Clarke's Red, Sandringham White. *Carrot*.—Early Short Horn, Main Crop, James' Intermediate. *Endive*.—Green Curled. *Leek*.—Musselburgh. *Lettuce*.—Wheeler's Tom Thumb, Giant White, All the Year Round. *Onion*.—Improved Reading, Naseby Mammoth, Webb's Banbury, Trebons. *Parsnip*.—The Student. *Parsley*.—Myatt's Garnishing, Carter's Fern-leaved. *Peas*.—William I., Carter's Stratagem, Carter's Telephone, Culverwell's Telegraph, Laxton's Omega, Ne Plus Ultra. *Rhubarb*.—Albert, St. Martin's. *Radish*.—French Breakfast, Scarlet Turnip, Chinese Rose. *Spinach*.—Round and Prickly. *Tomato*.—Carter's Green Gage, Vick's Criterion, The Conqueror. *Turnip*.—Carter's New Jersey Lily, Snowball, White Stone, Chirk Castle. *Vegetable Marrow*.—Custard, Moore's Cream.—J. MUIR, *Margam*.

ZYGOPETALUMS.

ORCHIDS might be appropriately and popularly classified in three sections that would better indicate their respective value to growers than do the more exact botanical system in use. The first and most important section would include all the numerous useful Orchids—namely, those that are easily grown and have handsome flowers borne freely; the second would contain such species as have beautiful but rarely produced flowers, and are difficult of culture; the third I should appropriate to the Orchids remarkable for structural or other peculiarities. Where only a few of the abundant forms in cultivation can be grown the selection is generally made from the useful section, but where the proprietor's means and enthusiasm are greater the others will be also deservedly represented. Fortunately really useful Orchids are now by no means scarce, and a collection of moderate size may be formed containing species and varieties that will maintain a succession of charming flowers through a large portion of the year. During winter flowers of all kinds are particularly acceptable; and in consequence, with Orchids as with other plants, those which flower at that time and possess some attractions are invariably greatly admired—more, perhaps, than they would be at any other period, for when the blooms are abundant the beauty of all except the most showy species is necessarily somewhat paled. Among the useful Orchids that are further recommended by their habit of flowering in the dull season the genus *Zygopetalum* is especially noteworthy, as it includes several species which, though not entitled to rank with the most brilliant of the order, yet possess a distinctive beauty that is scarcely surpassed. They are also marked by their freedom of growth and the durability of the flowers; and though the forms are not equally attractive they are all worth growing, particularly those which bloom about the present time. Such being their recommendation to notice, a few remarks regarding their culture, history, and characteristics may be serviceable to anyone who has not grown them, or only one or two of the best known forms.

Zygopetalum is a genus of terrestrial and epiphytal Orchids inhabiting tropical South America, Brazil being the head quarters, one species only extending the range to Africa. Nearly twenty species and varieties have been enumerated in cultivation, but some are rare and others not very attractive, though a dozen admirable forms can be selected. The genus was founded by Sir William Hooker, who gave the first technical description, the name being derived from two Greek words, and refers to the union of the petals below—one of the distinctive characters. It is included in the tribe Vandeeæ. The cultivation, as already indicated, is easy, all of the forms succeeding under culture in pots in an ordinary warm Orchid house. Similar temperature to that afforded *Cattleyas* suits them admirably, with a soil of peat, sphagnum moss, and charcoal broken finely, the drainage being very carefully attended to. During growth they need abundance of water, but when matured

the supply can be considerably reduced, though sufficient must always be given to preserve the handsome evergreen plaited leaves in good condition. Several of the species, notably *Z. Mackaili* and *Z. maxillare*, do not require a house specially devoted to Orchids, as they thrive in a plant stove or even in a vinery, the former plant being the better adapted of the two for such houses. The following brief descriptions will indicate the principal characters of the most beautiful species:—

Z. Mackaili.—Probably the most useful of the genus, and not inferior to any in attractiveness. For flowering at this time of year and in the winter months generally it cannot be surpassed,

Fig. 106.—*Zygopetalum Mackaili*.

the long spikes of fragrant flowers being very freely produced, and continuing in good condition for a long period. The accompanying engraving (fig. 106) well represents a single flower of the usual size, which was taken from a plant last week. The ground colour of the sepals and petals is a greenish tint, which is blotched and barred with a rich shade of chocolate; but the lip is the most striking portion of the flower, being beautifully streaked and marbled with bright bluish purple on a white ground—a most dis-

Fig. 107.—*Zygopetalum maxillare*.

tinct and effective contrast. The species is also interesting as the one that was first known, and upon which the genus was founded. It is a native of Brazil, whence it was obtained by Mr. Mackay of the Dublin College Botanic Garden, who forwarded a flowering specimen to Sir W. Hooker in 1827, from which the generic diagnosis and an admirable coloured plate were prepared for the "Botanical Magazine."

Z. maxillare.—Another very handsome species, which flowers at different times of the year, but generally during autumn. The flowers are borne on spikes, but not so long or erect as in *Z. Mackaili*, but they are equally as durable as those of that species. The sepals and petals are of a greenish hue with chocolate markings, especially near the base; the lip, however, is again the most striking portion of the flower, though it is very different in form from that previously described. It is a rich blue in colour, and is at the base peculiarly raised and ridged, so as to bear some resemblance to the lower jaw of an animal, and to this circumstance it owes its specific name. Fig. 107 shows the character fairly. The plant is a native of the Organ Mountains, Brazil, where it is said to grow solely on the stems of Tree Ferns, but it does not require epiphytal treatment in this country. It has been in cultivation about fifty years.

Z. Sederi.—Following the two best-known species I may give some description of this beautiful hybrid. It originated a few

Fig. 108.—*Zygopetalum brachypetalum*.

years ago at Messrs. Veitch's nursery, Chelsea, and was the result of a cross between *Z. Mackaili* and *Z. maxillare*, forming, I believe, the first hybrid obtained in the genus. It possesses some characters of each parent, being as free in growth and flowering, but

Fig. 109.—*Zygopetalum cochleare*.

rather dwarfer in habit. The flowers are large; the lip being particularly broad, and of a rich purple colour most beautifully mottled with a lighter tint.

Z. Clayi.—This I have not seen, but it has been described as a hybrid of similar parentage to the one last named, and is said to have been raised by Lieut.-Col. Clay of Birkenhead. An experienced Orchid-grower, however, informs me that it is only a variety of *Z. maxillare*. It appears to be of stronger growth than that species, and has spikes bearing about half a dozen flowers each, with brown-marked sepals and petals and rich purple lips.

Z. brachypetalum.—A species well worth more attention than

it has hitherto received, for it has the most pleasing characters of the genus strongly marked. The form of the flower is shown in fig. 108, the sepals and petals being a brownish tint marbled with green, and a violet-blue lip veined with white, and a purple-streaked column. It is also a Brazilian species, and has now been known nearly forty years. It usually flowers in the autumn or early winter.

Z. Wendlandi.—A handsome species of comparatively recent introduction from Costa Rica, and one which I understand we owe to Messrs. J. Veitch & Sons. It is similar in habit to those already described, the flowers being of good size, the sepals and petals olive green, the lip large, purple, with a white crisped margin. They also possess an agreeable fragrance.

Z. rostratum.—One of the oldest forms in English gardens, as it was introduced a few years after *Z. Mackaili*. It is entitled to rank among the most showy and useful of the genus, as it flowers at two or three different periods, the blooms lasting in some instances for five weeks. A slightly higher temperature than that suited to the other species with proportionate moisture is beneficial to *Z. rostratum*, and it will then amply repay the cultivator. The sepals and petals are yellowish green, but the lip is very distinct, the ground colour being white streaked with rosy pink.

Z. cochlear.—This is easily recognised by the flowers being produced singly and not in spikes or racemes, the prevailing character. The flowers are also individually distinct from other forms in the genus both in shape and colour. The bloom shown in fig. 109 clearly portrays the peculiarity of form, the sepals and petals being white, of wax-like texture and gloss, and the large lip veined with rich bluish purple. The fragrance is powerful and pleasing, and, though the plant is not so effective as some of its congeners, it well deserves attention. The usual flowering period is autumn, and the plant was obtained from Trinidad many years ago, but it is now rarely seen.

The other species included in this genus it is unnecessary to describe in detail. Those already mentioned suffice for ordinary collections, and where more can be grown *Z. africanum*, *Z. aromaticum*, *Z. gramineum*, and *Z. Gautieri* may be added. They are all more or less attractive. Some distinct varieties of *Z. Mackaili* and *Z. maxillare* are also known, but they do not demand special attention in these notes, as the remarks under each of these species sufficiently indicate their chief characteristics.

—L. CASTLE.

CHRISTMAS ROSES are deservedly general favourites, and, early as they flower naturally, with a little assistance they may be had in fine condition from the middle of December. One of the best varieties for this purpose is *HELLEBORUS NIGER MAXIMUS*, for the flowers are of great size, excellent form, and of a very clear white. The specimens from Chiswick at the last meeting of the Royal Horticultural Society well indicated the beauty and value of the plants when in good condition. These specimens were in baskets, and had been taken from the ground about a month previously, and when placed under glass soon commenced expanding their flower buds. A rich soil and frequent supplies of liquid manure had also assisted them greatly.

— WE learn that the TESTIMONIAL TO MR. PETER GRIEVE which was recently projected has taken the form of a gold hunting lever watch, a timepiece, and a pair of candelabra, with a silver cake basket for Mrs. Grieve, which were presented at a dinner in Bury St. Edmunds last week. In addition to the above Mr. and Mrs. Grieve have received a testimonial from forty-seven householders in the village of Culford, and also one from the under gardeners at Culford Hall.

— MR. WILLIAM PAUL'S ROSE ANNUAL for 1880-81, has been received by us, and a beautiful issue it is. The number contains coloured plates, admirably executed, of four Roses. Lady Sheffield, raised by Mr. R. B. Postans, is a grand symmetrical flower, with stout smooth petals of a pale crimson hue—

such a bloom as exhibitors would covet for making up a high-class stand. Princess Marie Dolgorouky (Gonod) is a vigorous Hybrid Perpetual, showing great substance of petal, colour rosy crimson. Madame Oswald de Kerchove (Schwartz) is charmingly represented, and as a Hybrid Perpetual is most distinct, the prevailing colour being white, but the centre of the bloom coppery yellow. If this variety will flower under ordinary culture as fully as shown in the figure it will prove a valuable addition, and indispensable for garden decoration. The remaining figure displays a grand bloom of Red Gauntlet (Postans), glowing scarlet crimson, with petals of velvety texture and fine foliage. It is as a bedding Rose that Mr. Paul thinks this Rose will be most valued, on account of its free growth and floriferous character; but it will be seen at exhibitions also. The number contains several excellent articles that all Rose lovers should read, and it concludes, as stated in the preface, the second series of the work; the two series now published containing thirty-two coloured plates of superior Roses, and constitute a work that certainly combines "beauty with utility."

— A GRACEFUL and distinct new Fern has been for some time in the possession of Messrs. J. Veitch & Sons, Chelsea, and probably the general public may have an opportunity of seeing it at some of the metropolitan exhibitions in the coming year. It is named *GYMNOGRAMMA SCHIZOPHYLLA*, and has elegant tripinnate fronds with linear dark green divisions, and the fronds are also remarkable for their viviparous habit, resembling in this respect some of the *Aspleniums*. It appears to be well adapted for suspending from the roof of a warm fernery, either growing in pots or baskets, as the fronds which are said to attain the length of 2 feet then arch gracefully. It is a native of Jamaica, whence it was obtained chiefly by the efforts of the late Mr. Arthur Veitch.

— THE demand for GOOD GRAPES appears to be considerable in the north of England, as we learn from a Durham paper that our correspondent Mr. Witherspoon has sold his crop of 1600 bunches, and intends erecting more structures for providing a larger supply. Grape culture appears to be more lucrative than Pear-growing, as we observe the projected alterations necessitate the disposal of several fine Pear trees five and six years old, of the most approved varieties. We have rarely seen finer Grapes than those grown in the "Red Rose Vineries" at Chester-le-Street, and we are not surprised at their ready sale.

— AT the central offices of the General Horticultural Company, Warwick House, Regent Street, we noticed last week three ITALIAN BOUQUETS of great size and tastefully arranged. Mr. J. Wills informs us that they were obtained from Turin, and though they were seven days on the passage the freshness of the flowers was surprising. They were each about 2 feet 6 inches in diameter, and were composed of pure white and crimson striped Camellias, Neapolitan Violets, *Hebeclinium ianthinum*, and the berries of a *Cratægus* arranged in a somewhat geometrical manner in circles, diamonds, and angles. The contrast of the lavender blue *Hebeclinium* with the white Camellias was especially pleasing.

— "G. O. S." writes, "It is somewhat remarkable that whilst there are so very few berries on the Hollies, Arbutus, Yews, and Ivy, the SAVIN bushes, which grow abundantly in this part of the country near Grange-over-Sands, are densely crowded with berries, as you may see by the enclosed. *Cotoncaster microphylla* has also a fair crop of berries." The specimen sent bore a great number of berries—more, indeed, than we remember having seen on so small a spray.

— ONE of the prettiest Pompon Chrysanthemums we have seen this season is a new variety named LILAC GEM, flowers of

which have been sent to us by Mr. Cannell. The flowers are very small and admirably formed, with chaste reflexed florets forming two-thirds of a ball. The colour is very pleasing, and the variety will be valuable for bouquets and general decorative purposes. As evidence of the usefulness of Chrysanthemums for vase decoration we may observe that the flowers above referred to are still fresh, though they have been severed from the plant upwards of three weeks.

— LIKE the issues of previous years, Mr. Shirley Hibberd's old-established annual, the "GARDEN ORACLE" for 1881, contains a great variety of matter, seasonable and useful. It includes articles on special subjects, new inventions, well-selected lists of fruit, flowers, and vegetables, and a concise calendar of gardening operations for the different months of the year.

— "W. I." sends the following note on PRIMULAS AT READING:—"Several of the houses in Messrs. Suttons' nurseries are at the present time filled with some handsome Chinese Primulas. The idea of maintaining a lengthened display of Primulas with the help of early, midseason, and late varieties is rather novel, but, as demonstrated at Reading, is perfectly practicable, as Messrs. Suttons have succeeded in perfecting strains which, if sown simultaneously and grown under precisely the same conditions, will flower at very different periods. Added to this the plants are sturdy in growth and produce strong whorls of large well-shaped blooms of various, and in some instances very novel, colours. Great improvements have also been effected in the Fern-leaved Primulas, which will probably bring them into favour again. The old strains were considered faulty owing to the extreme length of the leafstalks, but the new strains are sturdy and compact. The only variety yet named is Rosy Queen, and this is the earliest to bloom. A house now full of plants is very effective. The flowers are large, of good form and substance, the colour being a very pleasing rosy pink. A house is also filled with Ruby King Primula, which will shortly be at its best, as hundreds of plants are fast expanding their richly coloured blooms. This is a very sturdy distinct variety, but requires a little heat to develop the flowers satisfactorily. Two other novelties to be distributed this season are Reading Pink and Pearl, which are varieties of great merit."

— PART V. of PAXTON'S FLOWER GARDEN contains coloured plates of *Nepenthes sanguinea* and *Clianthus Dampieri*, the former rather startling in the colour, and the latter well indicating the form of the flowers, but much inferior in colour and size to the specimens exhibited by Mr. A. Harding at one of the Royal Horticultural Society's meetings last year. The cultural instructions are clear, the "Gleanings" being also continued.

— WRITING upon the DISTRIBUTION OF PLANTS in Messrs. Cassell's "Science for All," Dr. Robert Brown has the following remarks concerning the rapid increase of some plants when introduced into other countries. After referring to the spread of the well-known American Waterweed in this country since 1847, he continues: "The common Sorrel (*Rumex acetosella*) has been introduced with grain into nearly every one of our colonies, and in New Zealand it is spreading with such activity that it would take possession of the fields did not the farmer find that in the struggle for existence it cannot bear up against the greater vigour of the white Clover, which soon kills it. Even the white Clover in one locality has its match in the Cat's-ear (*Hypochaeris radicata*), which in three years from its introduction into New Zealand has destroyed excellent pastures. The introduction of the *Anacharis* into Great Britain is paralleled by the introduction of the *Vallisneria* into the Hudson River, where in the months of August and September it almost stops navigation in places; or by the Watercress, which threatens to choke up the New Zealand rivers in the district of Canterbury. A Grass (*Stipa tenuifolia*) has invaded the

southern Russian steppes, and is rapidly displacing almost every other plant; while the Cardoon (*Cynara cardunculus*), accidentally introduced from Europe, now clothes almost to the exclusion of other plants whole leagues of the Pampas of the Argentine Republic and Uruguay."

— AT the last meeting of the ROYAL HORTICULTURAL SOCIETY OF IRELAND—Edward Perceval Westby, Esq., D.L., in the chair—among other communications letters were read from Messrs. Moore and Burbidge, Directors of the Glasnevin and University Botanic Gardens, expressing their acknowledgments for their election as honorary members of the Society; and also one from Mr. Roberts, head gardener to the Countess of Charleville, Charleville Forest, Tullamore, King's County, thanking the Council for the special award of the Society's large silver medal for the extraordinary, indeed marvellous, bunch of black Grapes (*Gros Guillaume*) exhibited by him at the Society's Winter Show of fruits, held last month in the Exhibition Palace, and further giving a few interesting facts with regard to the Vine that produced it, which appear worthy of being put on record. After giving, as requested, the exact weight of the bunch in question (26 lbs. 6 ozs.), Mr. Roberts proceeds to say—"Last year two bunches cut from the same Vine and exhibited in London weighed over 3 stone, or 42 lbs., and for these I was awarded a medal by the Royal Horticultural Society, South Kensington. I may, too, mention the fact, merely with a view to show what the Vine that bore those and the bunch exhibited on the 25th ult. has done—in five seasons it has borne nine bunches, the total weight of which was 165 lbs."—(*Irish Farmers' Gazette*.)

— THE OLIVE HARVEST.—The Naples correspondent of the *Daily News* writes:—"According to the last reports the Olives in the provinces of Puglia and Calabria are of unusually good quality. The temperature could not have been better than it was during the last six weeks—a period essential for the definitive ripening of the fruit, which in consequence is so firmly attached to the branches that none falls, and it can be plucked at leisure. In Calabria especially not an Olive has fallen, a thing that has not been noticed for many years, and if the weather continues so mild and without frost there is a certainty that the fruit will yield oil of exceptional quality and quantity. The markets at Gora and Galipoli are calm, with little business doing, and if no further reduction in price is verified it is only because the actual price of oil is already low enough for an abundant harvest, from which foreign countries have still to lay in their large stores. Reports from Spain, the Ionian Islands, Greece, and Tunis are also excellent; the last place will yield a harvest three times more than the average quality."

FRAGRANT ROSES.

MR. MUIR's commendation of *Niphotos* as the best Tea Rose may be true of its indoor culture or of its condition at Margam, one of the most genial situations in the kingdom, within a few feet of sea level, and sheltered alike from north, east, and west winds. But change the situation. Take a site like this more than 800 feet above the sea and exposed, except so far as some plantations shield us from the west and north winds. What would then be the reputation of *Niphotos*? I wish much that more attention were given to hardy Roses suited to open grounds, and which should also maintain the Rose's chief charm—fragrance. There is, I am glad to say, an increasing disposition to discard delicate and scentless varieties. It will add greatly to the value of the proposed catalogue by the Rose Society, if in the description it be stated whether the variety is or is not fragrant. If this is to be one of the qualities particularised I shall be glad not only to take some copies but to subscribe towards the expenses of publication.

We greatly want a work of the kind. One other point interests me—I wish that the absurd nomenclature could be revised. The Rose requires no dignities; she is queen of the garden, and to dub her with a string of minor appellatives is ludicrous. I have in my garden nearly a thousand varieties; they appear in my private

catalogue shorn of titular dignity, and where feasible I have banished courtesy prefixes. My Roses grow and bloom none the worse for this excision, and I am saved much useless labour and weariness. In truth the Rose seems all the better for a simple name. I have of course been compelled to maintain some of the tinsel decorations. Duchess of Edinburgh could not well be abbreviated, but Wellington sounds better than the Duke of Wellington, William Paul than Mr. William Paul. Who would say Mr. William Pitt, or add an empty honour to the name of Caesar? Madame Rothschild reaches the extreme of my respect; but I have Camille de Rohan, Marie Henriette, Marie Cirodde, Malmaison, and The Gloire.

One word more about fragrant Roses. Why do not our nurserymen distinguish in their catalogues those that are sweet? There could in any event be no difficulty in saying whether new Roses are scented when their introduction is heralded. It is a misfortune that a scentless Rose was ever allowed to live. We should in the garden have a Spartan code. Imperfect as well as worthless things should be sacrificed; every Rose bantling without perfume should have been cast away. The evil of propagating false flowers like Madame Rothschild cannot be remedied by an individual. But these spurious things are put under ban by the fair sex, and we shall in time remove the pretenders, and secure others of their form and colour and with any other good quality, while preserving the Rose's wondrous sweetness.

Is it impracticable to publish in the Journal in sections a full list of all scented Roses? If you can give the space it would be a labour of love to many to supply the material.—W. SIMONS, *Gwainarren, Merthyr Tydfil*.

EXTRAORDINARY TITHES ON FRUIT AND MARKET GARDENS.

As a great many readers of your valuable paper have to pay the above obnoxious impost upon fruit and market garden grounds, I think a few remarks upon the subject will interest them and be useful to all of your subscribers. Lord John Russell, speaking of this tithe, said, "It was a tax upon agriculture, and one which would prevent people from making those experiments in agriculture which would be to the advantage of this country." Everyone must admit that it is a discouragement of the above industries and a direct tax upon labour and capital, and this extra tithe distinctly acts as a bounty upon those foreign importations—viz., fruit, vegetables, and Hops. I will mention a few parishes where this extraordinary tithe is charged upon fruit and market garden grounds, to show the inequalities that exist, as well as being a prohibitory tax in some parishes. In Isleworth, Middlesex, the charge is 7s. per acre; at Limpsfield and Oxted in Surrey, 16s. 9d.; Eynsford, Kent, 7s.; next parish of Shoreham none, at same time a great deal of fruit grown in both parishes; Farnborough, Kent, 7s.; Sutton-at-Hone, 9s.; adjoining parish of Horton Kirby, Kent, none; Plumstead, 6s.; Erith, 10s.; Bexley, none; Hoo, near Rochester, 12s.; Cooling, a few parishes off, 4s.; Leeds, near Maidstone, 18s.; Canterbury, none; Orpington, 8s.; Westerham, 18s.; Chart Sutton, 8s. 6d.; Sutton Valence, 18s.; Cranbrook, none; and St. Mary Cray, 8s. These parishes are all in Kent. In Sussex—Lancing, 6s. per acre; Henfield, 4s. 6d.; Edburton, 4s.; Thakenham, 3s. 6d.; and Offenham in Worcestershire, 4s. It must be remembered that this tithe is in addition to the ordinary tithe, which is generally about 7s. or 8s. per acre, a few parishes as high as 15s. per acre; and the corn averages, which are taken so unfairly and are now agitating the mind of every occupier of land, is charged upon these tithes. Thus last year, one of the most disastrous upon record to the producer of food, we were compelled to pay £111 15s. 1½d. for every £100 worth of extraordinary tithe, or 11½ per cent. above par. As Dean Swift tells us that the man who makes two blades of grass spring up where there was only one before is a benefactor of his species, so is a statesman who is a means of getting an Act of Parliament passed for the redemption of a tithe that prevents the tiller of the soil to a great extent in producing the fruits of the earth.—ALBERT BATH, *Colgates Farm, Sevenoaks, Kent*.

[Our correspondent is the author of a prize essay on "Tithes, Ordinary and Extraordinary, and How to Deal with Them," that has lately appeared in the *Mark Lane Express*. The theme is ably handled, and forms a practical and lucid treatise upon a complicated and difficult subject, and deserves a careful perusal. In dealing with extraordinary tithes he recommends "A short Act of Parliament, to be called the 'Extraordinary Tithes Compulsory Redemption Act,' should be passed, declaring that at a certain period all extraordinary tithes shall be redeemed, landowners in a reasonable time to pay the receivers of these tithes (who are with few exceptions clergymen of the Church of England) life and vested interest, it to be compulsory upon receivers of tithes to sell, Government to grant loans to the landowners where required upon

easy terms for the purpose of redeeming the said tithes. After the passing of this Act any agreement or lease binding the tenant to pay the landowner an extra sum per year in 'consideration' of being relieved of these tithes will be useless, and of no effect in courts of justice." The subject is undoubtedly one of great importance, and demands the consideration of all who are identified with the culture of fruit and other market garden crops.]

THE SCHOOLMASTER APPLE.

THE following figure of this handsome new variety is extracted from the "Gardener's Year Book" for 1881:—

"Fruit conical, obtusely ribbed on the side, terminating at the eye in broad ridges, and knobbed at the base. Skin bright green, changing to greenish yellow as it ripens, covered all over with large russetty freckles, and with a pale thin red tinge where it is exposed to the sun; russetty round the stalk. Eye closed, with long pointed

Fig. 110.—Schoolmaster.

segments, the tips of which are reflexed, set in a pretty deep basin; tube long, funnel-shaped; stamens marginal. Stalk very short, slender, or a mere knob, deeply inserted in a close cavity, with a large swollen protuberance on one side. Flesh white, crisp, tender, and mildly acid with some sweetness. Cells of the core open.

"A very excellent culinary Apple, which received a first-class certificate from the Royal Horticultural Society, November 16th, 1880. It was introduced by Mr. Thomas Laxton of Bedford, who reported to the Society that it was raised from seed of an Apple imported from America."

PEACH BLISTER AND POTATO DISEASE.

I DO not think there is so much difference of opinion between Mr. Luckhurst and myself about the question of Peach blister. I have no doubt that cold winds and severe changes of temperature predispose the trees to the disease; but, as in the case of the Potato disease, I still think the disease itself is caused by the growth of a fungus—in other words that fungus is the cause, not merely the result of the disease, both in the case of the Peach blister and of the Potato disease. I quite agree with Mr. Luckhurst that properly arranged glass walls will prevent the disease, and that with judicious management much may be done merely by a glass coping and shelter by means of Nottingham net, frigidome, or other materials to check the spread of it, even where there is no artificial heat used. Though well-ripened wood is less subject to the attack of the fungus, yet, under unfavourable conditions in the early growth of foliage in the spring, the disease will attack even the healthiest growths from wood of the previous year; but at the same time Peach trees that have the advantage of growing under glass, whether in heated or unheated structures, are less likely to suffer from the disease, both from their growth being better matured, and also because proper ventilation can be given without cold draughts and excessive changes of temperature which unprotected trees are liable to suffer from, and which both induces the disease in the first instance and promotes the spread of the blister afterwards.

With regard, too, to the Potato disease, I quite agree with Mr. Luckhurst that in favourable situations and in good soil, where the earlier varieties of Potatoes can be grown, that the spread of the Potato disease may be much arrested, and even in some cases prevented, by early raising the crop and securing it in dry sheds under cover, where it can be sorted over from time to time; but I cannot accept it as either a cure or a remedy for the later varieties when once the haulms are attacked, though it may often be a good plan to pull the haulms up and cover the ridges with fresh soil and to allow the ground to become drier before lifting, for if once the haulm is attacked it generally spreads through the whole of the crop, and no healthy growth can take place afterwards. I have

no doubt, too, from my own experience that careful storing and selection of sets, proper preparation of the soil, all manure being forked in, and the ground made ready the previous autumn or in early spring, and sufficient space being given between both the rows and the sets for proper air and sun, will help to ward off the attack of the Potato fungus, unless the weather be very favourable to its growth at the latter end of July or the beginning of August, when too often in such seasons as that 1879 all previous care and attention has proved unavailing. There is an adage, "A man convinced against his will remains of the same opinion still;" and I am afraid I must still say after all that has been advanced, that I still think the fungus cannot be said to be the result only of a

Fig. 111.—MR. ARTHUR VEITCH.

previously diseased condition, but that the growth of the *Peronospora infestans* is the actual means whereby the Potatoes are injured and become by degrees unfit for use.—C. P. P.

[We think the subject has been sufficiently discussed at present.—Eds.]

THE LATE MR. ARTHUR VEITCH.

SINCE we announced the sudden death of this gentleman, which occurred on September 25th last, we have received so many letters alluding to the sad occurrence, and so many expressions of respect for his memory, that we are sure his portrait will be welcomed not only by the great number who had the pleasure of

his acquaintance, but by thousands of others with whom his name and good works have become familiar. We quote from one of the letters referred to because it was the last we have received, and as a spontaneous expression of feeling of an old correspondent, who was quite unaware of the preparation of the portrait. After referring to the losses of the year and paying a warm tribute of esteem to the late Mr. Radclyffe, Mr. A. B. Stewart, and others, "D., Deal," wrote as follows:—"Few deaths have occasioned a wider feeling of regret than that of young Arthur Veitch—a proof of how true Christian life does commend itself even to those who cannot understand it. Modest and retiring, yet how highly he was esteemed! and devoting as he did so much time and thought to the sufferers around him, it was a

gratifying though sad testimony to his worth that thousands of the poor of the district in which he lived saw him laid in his grave, and that, as it was described to me, it was as a wall of tears; and this, let it be remembered, not so much a proof of gratitude for temporal aid as for spiritual teaching and ready sympathy in sorrow." We have nothing to add to those words, but may remark as evidence of the great respect in which Mr. Arthur Veitch was held by those with whom he associated in daily life, that the *employés* of the firm have in course of completion a handsome marble memorial for the grave of their lamented friend, with a suitable inscription including the singularly appropriate words—

"To live in hearts we leave behind, is not to die."

PORTRAITS OF NEW AND NOTABLE PLANTS.

ARCTOTIS ASPERA, VAR. ARBORESCENS.—"The genus *Arctotis* is little known to horticulturists, although one species, the present, of the thirty described, has long been known in botanic gardens, and no less than thirteen are figured in Jacquin's "*Hortus Schoenbrunensis*," from specimens that flowered in the Imperial Botanic Garden of Vienna during the last century. Sixteen (exclusive of one referred to *Venidium*) are enumerated in the "*Hortus Kewensis*" as being in cultivation in 1813, and there are five others enumerated as species in that work which are now regarded as varieties. The present is one of the most beautiful of the genus; it was cultivated in England before 1710, and in Holland much earlier.—(*Bot. Mag.*, t. 6528.)

DISA MEGACERAS.—"It is not without great consideration that I have been compelled to give a new name to the little-known *Disa macrantha* of the gardens, nor would I have done so were I not well assured that the true *D. macrantha* is a very different plant, coming indeed from a very different part of the South African continent from that inhabited by the present species. It is true that of *D. macrantha* very little is certainly known; it is a species of Thunberg's, described in his "*Flora Capensis*" (page 33) as having the spur conical, shorter than the hood; the petals small, hidden under the hood, rounded at the base, falcately recurved in the middle, angled posteriorly, dilated retuse and crenulate at the end, the lip oblong acute, keeled, sub-erect, and the anther, &c., as in *D. cornuta*, than which the flowers are rather larger. Now if the figure of the plant here given is compared with this description and with the plate of *D. cornuta* in this work (t. 4091), it will be seen that in all those points in which *D. macrantha* differs from *D. megaceras* it agrees with *D. cornuta*, notably in the short spur, in the small petals falcately recurved, dilated at the apex, and hidden under the hood; in the oblong lip and very small broad anther; to which must be added that *D. macrantha* is a western plant of the Cape district itself, whereas *D. megaceras* is an eastern one."—(*Ibid.*, t. 6529.)

ERIGERON MULTIRADIATUS.—"One of the most beautiful of the alpine Himalayan Composite, but very variable and difficult to distinguish from forms of neighbouring species, especially of *E. alpinus*, to which small states of it approach very closely. *E. multiradiatus* is, however, in its normal state a much larger and handsomer plant, with the heads usually at least 2 inches in diameter, and of a bright purple colour. In rich moist soil old plants grow 2 feet high and branch very considerably, and the radical leaves disappear early, giving the plant a very different appearance from that of its younger state, in which the habit is scapigerous and the radical leaves copious. It is a native of grassy wet pastures along the whole length of the Himalayan range, from Kashmir, where it inhabits elevations of 7000 to 9000 feet, to Sikkim, where it ascends to 12,000 feet."—(*Ibid.*, t. 6530.)

WORMIA BURBIDGEI.—"The genus *Wormia*, a near ally of the familiar *Hibbertias* of our greenhouses, consists of about ten species of shrubs or trees with usually very handsome flowers and foliage, which extend from tropical Australia through the Malay Islands and Southern India to the Seychelles. Though known in Indian botanic gardens, the present is the only one that to our knowledge has ever flowered in Europe. It is closely allied to *W. subsessilis* of Miquel. *W. Burbidgei* is a native of northern Borneo, where it was discovered by the intelligent and successful collector whose name it bears when exploring the Bornean forests for Messrs. Veitch."—(*Ibid.*, t. 6531.)

DISA POLYGONOIDES.—"A very different-looking plant from the *Disa megaceras*, though agreeing in all generic characters most closely, and when more fully developed a very striking plant, the spike of orange flowers sometimes attaining a foot in length. *D. polygonoides* inhabits marshy valleys, and has a very wide range, from Grahamstown eastward to Natal; and from the number of collectors who have sent it, it would appear to be a very common Orchid. The tubers of the specimen figured were

presented to Kew by W. B. Lyle, Esq., of Kirkley Vale Estate, Natal, and flowered in September of the present year in the temperate Orchid house."—(*Ibid.*, t. 6532.)

SCUTELLARIA MOCCINIANA.

THIS is a very useful plant for the stove, and it succeeds in an intermediate house. It is easy of cultivation, and when well grown makes a fine display. It is suitable for room or table decoration, but when grown for this purpose four or five cuttings should be inserted together. The reason several are recommended to be grown together is because it is rather difficult to produce good bushy plants retaining their lower leaves suitable for these purposes. To grow this plant well, no stopping or pinching should be attempted after the cuttings are inserted; they should be grown on until they produce their terminal racemes of bright orange scarlet flowers, the throat being of a deep yellow. Under the pinching and stopping system I have hitherto failed to grow this plant well to be of much service for winter decoration. If propagated in spring, and the plants are pinched from time to time to form bushy specimens, it is seldom they produce good flowers. Cuttings should constantly be rooted and grown on strongly until they produce heads of flowers; by this means they can be had in succession through the greater part of the year. It is a free-flowering plant and adapted for blooming at any time. The time of propagation for autumn and winter entirely depends upon conditions and facilities for growing the plants. The system most practicable is to propagate a few every month, and the plants should never be stopped, but allowed to bloom. It is difficult to produce a good specimen, as its lower leaves are very apt to fall. It not unfrequently happens, when stopping is resorted to, that strong shoots spring from the base of the plant, 6 or 9 inches of the lower part of the shoot scarcely having a leaf; but such shoots if allowed to go unstopped produce excellent flowers.

Cuttings root readily in heat in sandy loam without a bell-glass or propagating frame if shaded from strong sun until rooted. Leaf soil added to good loam in equal parts, and plenty of coarse sand, will form a suitable compost, in which the young plants will do well. Liberal applications of water should be given while growing, with occasional supplies of liquid manure when the pots are full of roots. This plant is very subject to mealy bug and a small black fly, and if not well syringed red spider will establish itself on the under side of the leaf.—WM. BARDNEY.

A NEW MODE OF HEATING BUILDINGS.

MESSRS. J. WEEKS & Co., the eminent firm of hot-water engineers, have devised a mode of warming churches, schools, mansions, public buildings, and private dwellings, which appears to possess features of considerable value. It is compact and admirable in arrangement, as will be seen by the accompanying figures, which Messrs. Weeks enable us to submit, and it provides for the admission of warm instead of cold air into buildings; thus fresh air is being constantly admitted in the most agreeable manner—a matter of great importance. The system cannot be so well described and explained as by an extract from the circular that is issued by the manufacturers of the apparatus.

"The boiler is tubular, the apparatus economical in its cost and in its consumption of fuel; it is powerful, rapid in its action, and requires very little attention. The connections are so arranged that any number of rooms from two or three up to fifty or more can be warmed, and the whole or any number worked together or separately as required.

"Fig. 1 shows a section through the outer wall of a church, at a window. It will be seen that the wall below the window sill is built hollow, and that the recess thus formed is filled with hot-water pipes. The opening at the top may or may not be covered by an iron grating C. A is an opening into the church and closed at pleasure by a wooden flap. B is an iron ventilator just above the level of opening A, also closed at pleasure by a flap. This arrangement serves as a warming apparatus and ventilating apparatus combined—thus: In the summer, when the warming apparatus is not in use, the flap A is closed and the ventilator B remains open. The result is that cool fresh air enters at B, passes up the cavity through the grating C into the church above the heads of the congregation. In addition to this, the current of air would naturally follow the direction acquired in passing through the cavity for some height in the church, as shown by the arrows, and then disperse into an immense number of small currents and descend imperceptibly, thus avoiding the draughts so common and distressing in buildings devoted to public worship.

"In the winter when the warming apparatus is in use, the flap A being still closed and the ventilator B open, the result would be

the same, except that the fresh air would be thoroughly warmed by contact with the hot-water pipes before entering the church; thus entirely obviating the necessity which exists under most plans of warming for admitting cold air into the building for the sake of ventilation. In very severe weather, or while the heat is being got up before the arrival of the congregation, the ventilator B may be closed and the flap A opened. The result then is that the air in the church passes into the cavity at A through the coil, out into the church at grating C, and, this process being continued,

FIG. 1.

the church becomes thoroughly and efficiently warmed with great rapidity.

"Fig. 2 shows the section through the wall of a school, institution, or any domestic building at a window on any floor or landing.

The same description applies to this as to fig. 1, except that instead of the wall being built with a cavity, the window recess is carried down to the floor, and the pipes are covered by a wooden case, which can be made perfectly plain or highly enriched as its situation and surroundings may render appropriate.

"Among the advantages of this system may be mentioned the following. The pipes do not take up valuable space, as they do not project into the building beyond the inner line of the wall. All channels and gratings are dispensed with, and consequently

FIG. 2.

their cost. The pipes are placed in immediate contact with the greatest cooling surfaces—namely, the windows. It is not necessary to admit any cold air into the building, as the fresh outer air can be thoroughly warmed before being admitted."

Other advantages of this system are enumerated in the circular, but for detailed particulars it is better to write to Messrs. Weeks at their Works, King's Road, Chelsea, S.W.

KITCHEN GARDEN.

Forcing Department.—Continue placing fresh roots of Seakale and Rhubarb in the Mushroom house as may be necessary to maintain the succession, also plant Asparagus, supplying advancing crops with tepid liquid manure. Frames containing Asparagus will need night covering over the lights, and linings applied to the sides of the bed and frame to maintain the temperature. Admit air to this crop

whenever the weather is favourable, with a view to improve the flavour. Maintain the supply of Mustard and Cress by sowing at intervals. Introduce roots of Mint in boxes or pots to a house where there is gentle heat, assigning them a light position. Potatoes that have been placed in heat to accelerate their sprouting should, before they have made too much growth, be transferred to pits or frames, beds of leaves and dung being prepared for them covered with 4 to 6 inches depth of light rich soil, and when this is warmed through—the temperature not exceeding 75°—insert the sets about 4 inches deep and 15 inches apart. Earlier crops growing freely should be earthed up as needed. Probably the best very early crops are secured by placing three sets in 11 or 12-inch pots in Peach houses, and where several houses are started at intervals a succession of new Potatoes can be maintained for a considerable time. Peach houses in which forcing is being carried on are suitable for starting sets in, placing them rather thinly on a layer of leaf soil and covering lightly with that substance. Those previously placed in pots will now be growing vigorously, and should be earthed up by filling the pots to within half an inch of the rim with rich light soil. Potatoes require plenty of light and air, hence those in pits or frames will need careful attention as to ventilation, and must be well protected in case of frost. Dwarf Kidney Beans should be sown in pots at least once a fortnight, and earth up the plants advanced in growth, keeping them near to the glass, and when in flower supply weak liquid manure, maintaining a temperature of 60° to 65°. Sow Celery seed in pans for the first early crop, also Tomatoes, which should have a light position in a temperature not less than 60°. Prepare beds for Early Horn Carrots, Radishes, and Cauliflowers and Cos Lettuce, sowing the seeds as soon as the beds are ready. Endive, Lettuces, Cauliflowers, and Parsley in pits and frames should have as much air and light as possible during the warmest part of the day, taking care to have sufficient covering to exclude frost in severe weather. These remarks apply to plants now required for use. Cauliflowers under handlights or in frames for early summer should have air on all favourable occasions, also Lettuces in frames for early spring, as the hardier they are kept the more safely they will pass the winter.

FRUIT HOUSES.

Vines to afford ripe Grapes early in June must be started at once. The outside borders should have some protection, shutters or glazed lights are suitable. Supply water liberally to the inside borders for weak Vines; weak liquid manure at a temperature of 90° will prove beneficial. Economise fuel by having a bed of fermenting materials inside the house. Syringing will be required two or three times on fine days, and the maximum temperature must not exceed 65°, keeping it at 50° to 55° artificially. Maintain a mean temperature of 45° with a dry atmosphere. Where late Grapes are hanging on the Vines examine the bunches frequently and remove all decayed berries; ventilate freely on fine mornings with a little fire heat, and keep the house closed when the weather is damp. Vines from which the Grapes have been cut should be pruned. We advise cutting back to a plump bud as near to the stem as possible—indeed a modification of the close spur and the rod system, which admits of old enfeebled growths being removed and training young wood in their places. Cutting to the best bud will induce in course of time very long spurs, but then it is easy to encourage new growths. All loose bark should be removed, washing the rods with soap and water, and afterwards dress them with an insecticide. The border should have the loose surface soil removed, and receive a top-dressing of turfy loam 2 or 3 inches thick in which about 20 per cent. of crushed bones and wood ashes have been incorporated. The houses should be freely ventilated and kept cool.

Peaches and Nectarines.—When the blossoms of the trees started early in the month show the anthers, syringing them must be discontinued, but the borders should be damped in the morning and on bright afternoons, maintaining a night temperature of 50° in mild weather, and 5° less when severe, 55° by day artificial heat, or 50° if the weather be dull and cold, advancing to 65° from sun heat, not allowing the latter to be exceeded without full ventilation. Commence reducing the ventilation from 65°, but have the ventilators slightly open constantly at the upper part of the house. Turn on the heat

early in the day so as to allow of air being admitted, which is essential to the vigour of the flowers. Where the flowers are too crowded draw the hand down the back or under side of the trellis, which will remove some. Maintain a moist condition at the roots, and to weakly old trees afford liquid manure in a tepid state. When the pollen is in a matured condition apply it carefully to the stigmas with a camel's-hair brush, choosing the early part of sunny days for the operation. The trees to be started early in the new year should now be ready. If such is the case the house may be closed, ventilating freely above 50°, and employing fire heat only to prevent the temperature falling below freezing point. The border must be thoroughly moist; and if, as not unfrequently happens, the soil has shrunk from the walls, ram it well down before supplying water, or it will pass off without percolating through the soil. The trees may be damped on fine days in the morning and early afternoon. A covering of leaves or fern should be placed on the outside border, with a tarpaulin or shutters over at a sharp pitch to throw off rain and snow.

Continue pruning and cleansing the trees in the succession houses, not laying in the wood thickly, as to secure fine fruit of good colour and flavour it is necessary that the wood be stout, and the foliage have full exposure to light and air for the full development and maturation of the buds as well as perfecting the current year's crop. Most of the evils in Peach-growing arise from overcrowding the young growths and filling the houses with plants that necessitate the maintenance of too high a temperature for the Peach trees. This causes the buds to swell, and they are often checked by removing the plants and opening the house. All fruit trees require a long and complete period of rest to insure their continued health and fertility, and neglect in those respects is certain to be followed by defect in the crops.

FORCING HOUSES.

If the earliest Roses in pots be now placed in heat without pruning they will afford flowers earlier than those pruned, which may be introduced to heat to afford a succession. Tea varieties are unsurpassed. Niphetos is the best, flowering continuously, its fine white-pointed Magnolia-like flowers being always acceptable. Duchess of Edinburgh, bright crimson, is free and invaluable for early forcing; Madame Claveret, apricot-tinged salmon; Isabella Sprunt, sulphur yellow; Madame Falcot, pale yellow; Souvenir d'Elise, white; Marie Sisley, white; Mrs. Opie, rosy carmine; Monsieur Furtado, Mdle. Marie Amand, canary yellow; Perfection de Montplaisir, yellow; and Madame Alexander Bernaix, peach, are a dozen fine varieties. With a few of the freest-flowering Hybrid Perpetuals, such as Baronne de Rothschild, Alfred Colomb, Marquise de Castellane, Paulin Talabot, Boule de Neige, Comtesse d'Oxford, Sénateur Vaisse, Thomas Mills, Sir Garnet Wolseley, François Courtin, Comte Raimbaud, and Baronne de Maynard, a succession of flowers will be obtained, and be a welcome addition to the ordinary indoor flowering plants.

Regularly bring Hyacinths, Narcissuses, Jonquils, Tulips, and other bulbs into the house, placing them on shelves near the glass. At intervals bring in Rhododendrons, Azaleas, Deutzias, Prunuses, Spiræas, Dielytras, and Lilacs, syringing them occasionally; but do not maintain a very close humid atmosphere, as it will render the flowers less durable when cut or removed to the drier atmosphere of the conservatory. Lily of the Valley can scarcely be had in too large quantities either for conservatory or room decoration, or for cutting. Single crowns potted in cocoa-nut fibre refuse, or in pots or boxes, should be brought into heat regularly according to the demand, plunging them in bottom heat, and invert pots, pans, or boxes, over them to draw up the flower stems to a length of 4 to 6 inches, when they may be gradually inured to light. The bottom heat must be about 80°. Tuberoses should be potted in turfy loam with a sixth of well-decayed manure. Remove all the offsets, placing the roots beneath the soil, and plunge the pots to the rims in a bottom heat of 80° to 85°, giving no water until growth commences. Supply it moderately at first, increasing it as the growth progresses, being careful to have it of the same temperature as the roots. When in free growth afford weak liquid manure freely. A light airy position is necessary to insure sturdy growth, and the temperature should

range from 60° to 65° at night, and 70° to 75° by day. Pearl from its dwarf habit and pure white double flowers is the best variety.

TRADE CATALOGUE RECEIVED.

Osborn & Sons, Fulham, London, S.W.—*Catalogue of Vegetable and Flower Seeds.*

Jasminum gracillimum (G. G., Chichester).—Plants will, we believe, be ready for distribution during the ensuing spring.

Names of Conifers (Rev. H. Taylor).—All the sprays have been correctly named by the nurseryman's foreman as written in pencil on the labels; the names in ink are incorrect.

Cottager's Kale (Cottager).—Both the heads and the side growths are excellent when cooked, quite equal if not superior to the Curled Kale. Cottager's Kale is one of the hardiest and most productive vegetables that can be grown for winter and spring use. We observed some rows of it last spring affording valuable produce in a garden in the north, where all the other winter green crops, including Brussels Sprouts, were destroyed by the severe frost.

Piping Required for Heating (G. S.).—Had you stated the size of your house, the extent of glass exposure, aspect, and the heat you require, we could have answered your question more precisely. Under the circumstances we cannot do better than quote the reply that we gave to a correspondent last year on this subject:—"A good formula for finding the length of a 4-inch piping to heat a structure to any given temperature is to multiply the glass or exposed superficies in feet by eleven times the intended difference between the outside and inside temperatures, and divide the product by fifteen times the intended difference between the heat of the water (180°) and the air of the house."

Peas (Idem).—If you will inform us whether you require tall, medium, or dwarf-growing Peas, or some of each character, also whether you are prepared to purchase the new and necessarily expensive varieties, we will endeavour to answer your question. Without this information we are unable to do so usefully.

"Holy Ghost" Insect (Norfolk).—The small, white, midge-like insect to which you refer under the above name is probably *Aleyrodes vaporariorum*. The insects attack certain Ferns at Kew, and when the plants are moved "dart off," as Mr. Smith in his book on Ferns describes, "like a flock of white Pigeons." This insect used to be prevalent in the Cambridge Botanic Gardens, where it attacked the under sides of the leaves of Tobacco plants that grew in the houses; it also attacks Tomatoes and often injures them. The Fern *Nephrodium molle* is very liable to be infested with it, as also is the small evergreen stove plant *Oldenlandia Deppeana*. The insects can be destroyed by frequent fumigations.

Vines in Pots (Park Hill).—Whether the Vines will produce a satisfactory crop of Grapes next year depends entirely on the condition of the wood now. If it is strong and matured they may be expected to afford a fair crop, but not quite equal to that of the past season. You had better not destroy the roots to which you allude, but, on the contrary, mulch them with manure, and feed them liberally with liquid manure when the Vines are in full growth and the Grapes are swelling.

Protecting Roses (C. C., Donegal).—If the buds are inserted in dwarf stocks a little fern, straw, or stable litter placed over them during severe weather will prevent their being injured; if inserted in standard Briars they may be covered with a little hay, but in this case the Briar stocks are quite as liable to injury if the frost is intense as the dormant buds of the Roses. Unless the weather is very severe the dormant buds of Roses are seldom injured.

Garden Walls (Deodar).—If you send 3½d. in postage stamps to the publisher and ask him to send you No. 355 of the Journal you will find fuller instructions, with illustrations, on the subject in question than we can possibly afford you in this column. Glass copings are useful additions, but good crops of fruit are produced when the trees are protected with nets or other coverings in addition to the ordinary stone copings. When walls are wired their surfaces are preserved in better condition than when nails are being constantly driven in for securing the branches. If you use galvanised wire it will be prudent to have it painted. If you need further information we will readily supply it.

Cucumbers Gumming (T. C.).—Like Mr. Fish, whose experience you have referred to, we have had plants troubled with this disease, but, on adopting similar measures to those described in the article in question, it disappeared. It appears to be more virulent in your case, and we regret that we are unable to recommend any other remedy than that we adopted ourselves and the practice of another cultivator. We emptied the house of every particle of soil, burnt sulphur in it, washed every portion of brickwork with hot limewash, painted the woodwork, and used soil for growing the plants less rich and in less quantity than before. Dressing the affected parts with charcoal dust we have found of benefit; and Mr. Cooling of Derby, who used to grow Cucumbers extensively for seed, informed us that he had quite checked this form of disease by dusting the plants and also the bed frequently and freely with Amies' manure. This fertiliser, being a dry powdery substance, would, we presume, have the same effect on Mr. Cooling's plants as crushed charcoal had on ours, and you might well try the remedy; it could not possibly do harm, and might do good. You might also try the plan of growing the plants in large pots, but the roots permitted to pass over and through them into very rough soil, as practised so successfully by Mr. Coleman at Eastnor Castle, as referred to on page 336 in our issue of November 1st, 1877.

Culture of Herbaceous Calceolarias (D. Williams).—No artificial heat is required except to exclude frost. Keep your plants upon a light airy shelf near the glass. Repot from time to time as soon as the roots touch the sides of the pots in soil consisting of equal parts of loam and old rich manure, with about a fourth part each of sand and pounded charcoal, taking especial

care to use plenty of drainage. Attend well to watering, and fumigate with tobacco paper to keep down aphides. For large specimens it is necessary to nip out the centre of the plant to induce it to form a strong lateral growth. Cease repotting as soon as the flower stem begins growing, and then substitute cowdung water or sewage for the clear water. By close attention to this simple formula you may grow plants for exhibition with success and derive much pleasure from the work, for no plant with which we are acquainted rewards one better for care and attention than does this.

Tomatoes in Greenhouse (J. L.).—You will have sufficient heat in your house for growing Tomatoes, and a free-fruited and good variety for the market is the Old Red. If you require a crimson variety you may grow the Conqueror or the earlier but smaller Vick's Criterion. The best yellow-fruited variety is Carter's Green Gage. It is impossible for us to answer your second question, as everything depends on your skill as a cultivator and the demands of your neighbourhood. If you have never forced Kidney Beans your first attempt will possibly not prove so profitable as you anticipate, and if you have not had experience in forcing Potatoes you will possibly err by affording them too much heat. You wrote your letter so hurriedly that some words were omitted, and it is impossible for us to ascertain from it whether your large house is provided with bottom heat or not.

Grafting Pereskia aculeata (L., York).—Take off the head of the Pereskia at the required height, and make a slanting cut upwards, and about an inch long, at the top of the stock and on one side. You will cut off a stem or branch from the Epiphyllum to be grafted upon the Pereskia, and pare one side at the lower end in a slanting direction downwards, making it quite thin at the bottom, and so that the cut part shall fit that of the stock exactly. About half way down the slanting cut in the stock make a cut downwards, and about half an inch long, and make a corresponding one upwards in the graft, which will make a sort of slit or tongue in each; that of the graft should be introduced into the one in the stock, and pushed downwards, so that the cut portions of both may fit correctly. The graft may be fastened or bound to the stock with a strip of bast matting, still keeping it in its place and tying tolerably tight, but not very much so. The junction may then be covered with moss, binding it on with matting. It is not necessary to cover with clay. The plant may be placed in a house where there is a gentle heat, and graft and stock alike sprinkled with water twice a day by means of a fine-rosed syringe. When the graft begins to grow the matting should be loosened. The best time to graft is in spring, or a little before the Epiphyllum begins to grow.

POULTRY, PIGEON, AND BEE CHRONICLE.

LESSONS TAUGHT BY THE EXHIBITION OF FAT STOCK.

THE exhibitions of fat stock previous to Christmas at Islington, Bingley Hall, and the various large towns and districts throughout the kingdom, cannot fail to be instructive to inquiring men of business habits. The exhibitions are patronised not only by the wealthy agriculturists, but also by royalty and the nobility and gentry of the kingdom; and as this is the case the home farmer may feel assured that all the ability and experience which wealth can command has been applied to the breeding, rearing, and feeding of the best animals. Therefore the opportunity for men to learn in this branch of the agricultural profession is of the highest value, especially when we consider that the making of fat stock is the chief aim of the most important part of agriculture. The maintenance of the pastures, the cultivation of the land, the choice of seeds, both of roots, grasses, and green crops, as well as of a large portion of our pulse and grain crops, are performed with the view of providing for the live stock and preparing the land for the production of Wheat and other crops. It is therefore extremely desirable that the feeding of stock should be made profitable as a farming transaction, and in order to accomplish this the home farmer should certainly be allowed by his employer to visit these exhibitions. He must remember that he is differently situated from an ordinary farmer or occupying tenant, who has chiefly to look to profit alone; the home farmer has, however, to provide and feed stock which must be made profitable, but at the same time it must be ornamental to some extent in the park lands and pastures. These matters must also be arranged in accordance with the tastes of the employer, who may prefer particular breeds; and this must therefore influence the choice of stock, bearing in mind that during the year a considerable

proportion of the stock fattened will be required to supply the requirements of the establishment.

We will take it for granted that on visiting a well-conducted cattle show a lesson may be learnt in almost every class. We ask the home farmer to do as we have done for more than fifty years—not only to take particular notice of the animals which are distinguished by the award of a prize, but to satisfy himself of the reason why such an animal should have obtained the prize. This cannot always be done, except by reference to some experienced man, when it will be often explained without much hesitation, and must be remembered by the home farmer to serve him in his future transactions. One circumstance serves to confuse the mind of the novice—namely, the judges themselves do not always agree. Instances of this occurred in the awards at Birmingham and the metropolitan shows held lately, for the same animals exhibited at both exhibitions were differently placed by different judges. This has always been the case, owing in a great measure to the difference of the experience and tastes of the persons entrusted with the duties of judging. We will endeavour to show the home farmer the advantages to be obtained in viewing a cattle show at the present day as compared with former periods. We remember when the Smithfield Club Cattle Show was held in the Baker Street Bazaar, and we have reported upon their meetings under great difficulties compared with the present facilities. The stock, too, has greatly improved, for instead of the old animals of enormous bulk and weight we have now specimens with the flesh as even as possible, so that the animals not only look even to the eye, but when dead are found to have the lean and fat so well mingled as to constitute meat of the finest quality.

There is another great and distinguishing feature in our present exhibitions—namely, early maturity, which is a point of great importance. It began first to receive special attention about 25 years ago, and now cattle at two years old compete as fat animals; also in the sheep classes lambs born in the year are in a class by themselves. In the pig classes, too, early maturity is also encouraged. At Islington this year the Devons steers under two years old averaged about 74 stones of 8 lbs. dead weight, the Herefords 83 stones, the Shorthorns 97 stones, the Sussex also 97 stones. In these weights we have felt some disappointment, because in referring to our own list of Shorthorns of the same age we find that twenty years ago stock was sold at nineteen and twenty months old weighing from 98 to 100 stones of 8 lbs. carcase weight, besides large amounts of internal fat; the animals alluded to being ordinary Shorthorns without pedigree, but were very carefully box-fed, and were never off the straw during their life either in summer or winter. In making up our cattle for early maturity we never resorted to large allowances of cake, hay, &c., and during the second year of their life they received no more than 4 lbs. of cake and 2 lbs. of bean meal daily mixed with cut roots, no hay being used, only good sweet straw *ad libitum*. Our experience has taught us that young cattle are best made out at an early age by moderate feeding, and always under cover, so as to insure health as well as gradual increase of weight and condition. If we require a perfect fat animal it must be fat as a calf, and also at any other age to which it may be kept, to insure with the greatest certainty the greatest weight for age of the choicest quality. We cannot recommend any particular breed for fattening, because this must have reference to various circumstances. It must, however, be noted here that the crossbred cattle, say the first cross, such as the Shorthorn and Aberdeen, and others, have been successful at various times in carrying off the champion prizes at the Smithfield Club Show, and probably quite as often as any one of the pure breeds. To have the pure-bred animals is essential to producing a successful cross. It appears that it is not necessary to take pedigree stock for fattening for profit, but often the reverse, as the butcher only requires weight and quality. From all that we can glean after many years' observation we think it will prove very difficult to maintain the present pure breeds in their native excellence without deprivation, notwithstanding they may be reared within the lines of pedigree.

In referring to sheep at the fat stock shows lately held we cannot notice any improvement in the various breeds; still, the Hants Downs must not pass unnoticed, but even these have obtained more observation from the fact of lambs being introduced into the prize list at Islington. Mr. Morrison's lambs are worth the attention of the home farmer upon the lines of early maturity. We noted that the dead weight of these amounted to from 28 to 30 lbs. per quarter, or from 14 to 15 stones of 8 lbs., the probable age being about eleven months, and will be sold as ripe mutton. We do not notice that any lambs of other breeds or crosses are quite so heavy as the Hants Down, yet, as they usually fall later in the spring, those exhibited were no doubt younger

animals. These Hants Down lambs attract more notice than any other stock, and there is no doubt that they are better adapted for early maturity than any other pure breed; still we cannot forget the crossbred lambs exhibited at Easter for prizes in a southern county, which have frequently reached a dead weight of 10½ to 11½ stones of 8 lbs. at the age of five and a half to six months old, but raised from various crosses, such as down and Somerset horned stock, also Devon and Cotswold crosses. It is fair to infer that had these lambs been carried forward by good feeding until eleven months old they would have quite equalled anything yet exhibited, and probably surpassed it, both in weight for age and quality of meat. Swine will always be useful on the home farm, and it is of consequence for the home farmer again to notice those breeds which will yield the greatest weight for age of the best meat. Instead of adhering to any particular breed, whether of Berkshire, Sussex, Essex, Middlesex, Small White, or Large Yorkshire White, we should use the first cross, such as a Berkshire sow and a large Yorkshire boar, and a cross in the same way by the other smaller breeds, taking care, however, always to breed from stock having plenty of long soft hair, this being the best indication of a tendency to yield a good proportion of lean meat.

WORK ON THE HOME FARM.

Horse Labour.—Fallow-ploughing must still be continued until it is completed, and the sooner this is done the better, so that the soil may receive the usual benefit from frost. All strong flat-lying land should be ploughed a good depth, and have deep cross furrows, to be afterwards made with the spade somewhat deeper than the land furrows, in order that heavy rains may escape readily. When water is allowed to lie about on the fallows it hinders the work of early ploughing and cultivation in the spring. Carting ought now to be continued, in order that the farm horses may not be idle, which is sure to injure their health, because when they have been accustomed to severe labour during the summer and latter seedtime, if not exercised their legs often become swollen. Carting has reference to various necessities on the home farm, varying in different parts of the country. On farms with parkland and pastures attached all odd times should be occupied by collecting and carting earth and vegetable matter, as anything that will readily decay in heap will not only be found useful for application to grass land, but collecting them will tend to keep the roads, dykes, yards, and farm premises clean, and save an outlay for artificial manures in dressing the pastures. The depth of the fallow-ploughing is a matter of more importance than some persons admit, and farmers are often advised to plough deeply without reference to the nature of the subsoil. If we have to contend with a clay subsoil not rich in potash it is lost labour to plough deeply; in fact, every farmer should have an analysis of his subsoil before he decides what depth to plough the land. Again, in some instances, without reference to analysis, the subsoil is charged with weed seeds, or it may require a dressing of chalk or lime. We recommend that those soils which have a hard subsoil should be ploughed the usual depth only, but be followed in each furrow by the subsoiling implement, so that the crust below should be loosened without being brought to the top.

Hand Labour.—Some little assistance will be required by the shepherd and cattle man in cutting out hay and straw, preparing roots for the cutter, trenching in the meadows, hedging, and banking. Roadside work also should now be done, in order that the work of spring may not be displaced, because every period brings its work on the farm, and if any labour peculiar to it be omitted it will disturb the arrangements and cause extra expense. The old scourge, the foot-and-mouth disease, is now prevalent in various districts, and is daily spreading. It will be well to avoid purchasing fresh stock from the markets at present, for although the cattle may not show symptoms of disease yet they may be infected, and this disease is of such a nature that the men in charge of infected stock will often carry it in their clothes from one district to another. Extreme care is therefore necessary in all transactions where cattle and sheep drovers are passing to and from the markets. It appears from the veterinary reports that sheep and pigs are likewise infected; this makes the matter still more complicated and difficult to avoid. Severe losses occur through this disease; for although with careful treatment very few animals die, yet it often ruins a whole dairy of cows indirectly for years after it has disappeared. Foot-rot lameness is also increasing, especially where the sheep are being fed with roots upon wet flat-lying soils or on pastures. This, too, is a disease which spreads by infection, and sheep fed in troughs more often break down with foot-rot in consequence, and they should therefore be selected and kept separate if only a few are affected. If, however, the attack is general the animals should be driven to coop every day, and the diseased feet should be dressed as fast as they occur. This is the only way to keep it under. It is no use for the home farmer to say that the outbreak is too extensive to be treated with success, for unless it is met with good remedies and determined and careful dressings daily, it will very soon destroy the whole of the profit on the flock. Let us suppose with a flock of several hundred sheep that it is necessary to employ two men who understand the treatment every day for three months, what is the cost of the labour compared with the loss of the sheep if the disease is allowed to run its course

unchecked? We have had experience in this matter for many years, but we never hesitated to employ sufficient skilled labour to keep the disease under. Our remedy is as follows:—Take 3 ozs. of nitre, 3 ozs. of blue vitriol, 3 ozs. of coarse gunpowder reduced to a very fine powder, and well mixed with hog's lard; it will then keep ready for use. This we have found a satisfactory remedy for forty years past, but the sheep must be attended daily, the feet pared if necessary, and after the dressing to stand on dry straw for two hours.

POULTRY IN GARDENS.

FEW can deny that gardeners have generally regarded poultry with antipathy, but this, I am glad to say, is fast changing, and those who have to employ artificial heat are rapidly becoming aware that the heat conveyed into the hothouse and Orchid house may be profitably utilised in hatching chickens in the winter, and rearing them in the orchard house. They also erect their poultry houses close to the chimneys of the boiler fires; thus the heat given off causes the fowls to lay at a time of year when eggs are most valuable, and at the present time I am obtaining eggs of fancy breeds from gardeners who supply the London markets with early Cucumbers and hothouse Grapes.

It is well known that poultry like plenty of space and new ground; and turning this to account, one fruit-grower in Essex thought he would exhibit at a poultry show, and he was surprised upon visiting the show in the afternoon to see all his birds marked for prizes, and also to find that they were so much larger than any others exhibited. This, he assured me, was entirely owing to their early development in the spring months in the vineries. He had the earth forked up frequently under the Vines, and he did not find any ill effects from the small chickens. In fine weather the birds run out from the ventilators close to the floor, and soon find their way into their own house. In several instances where the eggs were set under hens, as soon as the chickens were hatched he moved the hen and coop into the vineries, and he hardly lost a chick. Birds as soon as they are hatched appear to hunt for insects, and when all is cold outside the house insects flourish within. Chickens cannot mount up to the fruit and to the shelves, therefore they content themselves with searching about on the floors and walls.

In America it pays well to have Turkeys driven through the crops of plants intended for seed, and over the tobacco fields. Ducks do a considerable amount of good in a garden, and it pays to allow a flock of them to pass through the beds, if the boys are watchful to keep them from eating the Lettuces and other tender plants. They do work which it is impossible to have so efficiently executed by any poisonous compound or lime, because they are provided with both sight and touch, which enables them to collect the small insects, and the more work there is to do the happier are the birds. I hope that gardeners reading these remarks will try and overcome their hatred of poultry, and endeavour to find them a corner in every establishment.—THOS. CHRISTY, F.L.S., *Malvern House, Sydenham, S.E.*

THE CLOSE OF THE SHOW SEASON.

THE chief events of the exhibition year are now things of the past. The real contest is over, but there are still some skirmishes, and even a sharp struggle or two yet to come. Our friends north of the border are a little later than we are down south, and there is yet a chance even in the south for the late-hatched and the late-moulted birds.

The new year opens in Scotland with the *Paisley* Show, which has thirty-two classes for poultry and fifteen for Pigeons, with five prizes in most of the poultry classes and four in all the Pigeon classes, with a great array of weather-glasses for special prizes. We presume our northern friends look anxiously forward for days free from mist, and that the thirteen weather-glasses will prove an attraction.

On the same day as Paisley another Scotch show, *Kirkcaldy*, is to be held. Here there are thirty-three poultry and seventeen Pigeon classes, with three prizes in each. Next comes the Show of the Northern Poultry and Pigeon Club at *Aberdeen* on the 6th, 7th, and 8th of January. This promises to be a really first-class show, as there are no less than fifty-seven poultry and twenty-four Pigeon classes. There are four prizes in each class (the fourth being a eard) and ten cups. Brahmas and Cochins seem to be hardly dealt with, as all colours have to compete together. However, we suppose that the Asiatics are not popular with the Aberdeen folk. We thought Scotch Greys might have usurped their place, but were surprised to find that they had not even one class. The entries have closed in the case of these three Scotch Shows, but we mention them so that such of our readers as are within reach of them may not forget to pay them a visit.

Kendal on January 13th, 14th, and 15th comes next on the list with fourteen cups, forty-three poultry and twenty-two Pigeon classes. Poultry have three prizes of £2, £1, and 10s., with an entry fee of 6s.; Pigeons a like number of prizes of half the respective amounts, and a 3s. entry fee. The entries closed on the 29th December. Messrs. Dixon, Addie, and Charlton judge the poultry, and the latter gentleman the Pigeons.

One day later than *Kendal* comes *Stockport*, with twenty open and twenty-four local poultry classes, with £2, 15s., and 5s. in the former, and £1, 10s., and 5s. in the latter. Pigeons have fifteen open and nine local classes, the prizes in both sections being 15s. and 7s. 6d. The entry fees are 4s. and 2s. 6d. respectively. There is a five-guinea prize point cup for poultry, and a similar £2 2s. cup for Pigeons. These cups may increase the entries, but they also lead to borrowing and are thus objectionable. The judges are not announced. The entries close January 1st.

Dorchester takes place on the 19th and 20th January. Here we have the promise of a good Show, as there are twenty-one cups, forty-five poultry, and sixty-six Pigeon classes, with three prizes of £2, £1, and 10s. in the former, and three of £1, 10s., and 5s. in the latter case. The entry fees are 5s. 6d. and 3s. 6d.; and the Judges announced are Messrs. Teebay and Dixon for poultry, and Messrs. Jones and Esquilant for Pigeons. Entries close January 6th.

Lincoln follows on the 22nd and 24th January. Poultry have twenty-four classes with four prizes of £1, 10s., 7s., and 4s., and an entry fee of 4s. Pigeons eighteen classes, with four prizes ranging from 15s. to 3s., and an entry fee of 3s. Messrs. Dixon and Smith judge the poultry, Mr. R. Woods the Pigeons. The entries close January 10th.

Next on our list comes *Liverpool*, which is to be held under Poultry Club rules on the 26th and 27th January. It is, we believe, some years since a show was held at Liverpool, and the schedule is a modest one. There are twelve cups with thirty-eight classes for poultry, the prizes being four in each class, and ranging from £1 downwards. The entry fee is 4s. Mr. Horsfall is to judge the Brahmas; Mr. Cresswell the Cochins, Dorkings, Hamburgs, and Leghorns; and Mr. Teebay the remainder of the poultry. Pigeons have fifteen cups and specials and thirty-one classes, the prizes here being 15s. first down to 4s. fourth, with an entry fee of 2s. 6d. Mr. Cresswell judges the Turbits and Fantails, Mr. Graham the Dragoons, and Capt. Heaton the remainder. We trust our Liverpool friends will have a good entry, and that the Show may become a fixture. The entries close January 5th.

Wolverhampton ends our list, and is regarded as one of the leading events of the year. Poultry Club rules are here also in vogue. There are twelve cups for poultry and Pigeons. Poultry have fifty-one classes with liberal prizes, and the classification is improved, there being now separate classes for old birds in some varieties which had in former years to compete in pairs. Pigeons have twenty-three classes with four prizes ranging from £1 downwards. Mr. Lane judges the Game and Game Bantams; Mr. Cresswell the Dorkings, Brahmas, and Cochins; Mr. Dixon the remainder. Mr. E. Hutton of Pudsey, Leeds, takes the Pigeons. The entries close January 19th. We have now noted all the forthcoming Shows of importance except perhaps Cambridge, which is to be held the days immediately preceding Wolverhampton, and the schedule of which has not yet reached us.

THE SCOTCH GREY FOWL.

READERS of this and other papers are frequently asking which is the most profitable fowl to keep; and I think, if the Scotch Grey cannot be said to be the most profitable, it may at least be named as one of the best. To rear for table or keep for laying they are most satisfactory. Young cockerels six months old weigh as many pounds, and by the time they are fully matured they will turn the scales at 10 lbs., and this with flesh of the Dorking or Game fowl texture and flavour. The hens average from 6 lbs. to 8 lbs., and they are capital all-the-year-round layers. In my opinion the best way to secure this very desirable quality is to have a hardy fowl, as tender varieties never lay well in severe weather; and it is in this the Scotch Greys possess great advantages, as they are extremely hardy and not readily influenced by sudden changes of weather, nor do they appear the least subject to early infirmities, as I have hens over three years old now as hearty and laying as well as one-year-old pullets. They are easily reared, feathering quickly, and taking good care of themselves. They have not the same rambling inclinations as Hamburgs, and they succeed remarkably well in confined runs—a circumstance not to be wondered at, as their hardy character easily accounts for it.

As these remarks apply chiefly to their value for table and

laying, it will hardly be necessary to say much respecting their exhibition qualities; but here again they are not deficient, as they are beautiful birds in the show pen, and in Scotland they always head the list at the best shows. At the late Edinburgh Show there were 130 pens of Scotch Greys, which proves that in the north they occupy the position they so well deserve.

True birds have a Dorking-like head, and evenly dappled grey or cuckoo colour. The legs are generally the same colour until the birds are a year old, when they become quite white; and in this respect they differ widely from the Plymouth Rocks, which they otherwise somewhat resemble, as the legs of the latter are so yellow that they are not readily disposed of in market.—J. MUIR, *Margam*.

SMALL POULTRY YARDS.

I SHOULD be much obliged to "M. M." if he would give some more minute details concerning the fowl yard of Mr. Clatworthy. The whole yard appears (see page 560) to be 42 feet long by 27 broad; if out of this there be taken a grass plot 27 by 12, and a 2-foot path all round it, there is left a space of $5\frac{1}{2}$ feet. The circumference being divided by 12 gives to each run a space of about 12 feet by $5\frac{1}{2}$. Is the whole of this space roofed-in and divided? If so, is it divided by boards, with only wire in front? If only the roosting place is roofed-in, what is its size? Then again, "M. M." speaks of the top range being divided into twelve coop-like runs. I hardly know what a run would be like to resemble a coop, and if by the top range is meant a space at the end 27 by $5\frac{1}{2}$ I cannot see of what use this would be when divided by 12 for rearing chickens. Would "M. M." or Mr. Clatworthy furnish a drawing of the runs and roosting places, so as to give others an opportunity of following so good an example?—C. J.

EYMORE BLACKS.

MR. T. C. BURNELL, in the pages of a contemporary, states his reasons for giving these birds a prize at Birmingham. He had awarded one prize to La Flèche and another to Plymouth Rocks, then he had to find a third-prize pen. The representatives of other known breeds present were defective in one characteristic or another; and although he might have gone to a second pair of good La Flèche, he considered that "this would be making it pretty much a La Flèche class," and it has always been his endeavour in a mixed class to distribute the prizes as equally as possible. He has always understood the Variety class to be meant especially for any new variety. The clean-legged Langshan-like fowls called Eymore Blacks were in brilliant condition, and were perfectly new to him. He could not see any other pen particularly deserving a prize, so he gave the third to the Eymore Blacks.

The explanation renders the Judge's method of reasoning which led to award the prize plain to all, but we must say that we cannot agree with Mr. Burnell. We think a judge who undertakes to award the prizes in a Variety class should make himself acquainted with every known variety, and that an exhibitor who in these days of easy diffusion of knowledge hides his newly found treasures under a bushel until they appear in the show pen ought to expect to have them passed over by the judge. It is manifest that the system of awarding a prize to a bird simply because you have never seen its like before is an erroneous one. The exhibitor of known varieties is obliged to at least approximate to a standard, and is thus placed at a most unfair disadvantage as against the exhibitor of a breed which may have come from "a hitherto unknown port of the Black Sea," as Mr. Burnell jocosely puts it, but the points of which are as unknown to the judge as the port in question to the geographer. Will the exhibitor tell us something about these Eymore Blacks? We would suggest as a heading for his communication, "Results of a Cross between a Langshan and a Dorking."—A FANCIER.

EFFECT OF HENBANE ON FOWLS.

IN your issue of December 2nd I read with much interest your answer to a correspondent on the effect of Foxglove on fowls. Of that plant I have not had any experience, but I can speak of the Henbane, which is a very destructive plant to poultry generally. A friend lost two Ducks full grown without being able in any way to account for their deaths. These Ducks had been to the bottom of the grounds where Henbane was growing, and there also was a fowl house in which a few fowls were kept, one of them a great pet. At feeding time this pullet could not be found, but on looking into her roosting place she was discovered standing up with her neck stretched out and her beak resting on

the ground as if all spinal power was gone. She was taken in and dosed with brandy and water for two days; she recovered, and is now strong and well, and was able to make her appearance in the show pen. The Ducks had no antidote administered, and therefore paid the penalty of their greediness. A few days after this occurrence I read the following in a French poultry book:—"The Jusquame, a poisonous plant very common in our villages, and unfortunately much sought after by Ducks, Geese, and other fowls, is mortal to them all. It is this Jusquame noire, which the English designate by significant appellation of Henbane, otherwise poison for hens."—LA FLÈCHE.

VARIETIES.

WE understand that the last Committee meeting of the Poultry Club for this year was held yesterday (29th) at Oxford.

— HEREFORD POULTRY FAIR.—Probably the largest poultry market or fair held in the kingdom is that which takes place at Hereford before Christmas. It was held on Wednesday in last week, and in spite of most unfavourable weather the city was thronged with visitors to it. The following is from the account of it in the *Hereford Times*:—"Hereford Christmas poultry market has for an age been famous for the great quantity, fine quality, and exceptionally good dressing of poultry. In the arts of breeding, plucking, and dressing, the Herefordshire farmers' wives and daughters have always carried off the palm, though the scalding and drawing of the poultry, while giving a fine and tempting appearance to it, does not allow of its preservation for such a length of time as when it is not drawn. This objection, however, cannot have much weight when the market is so near Christmas day. The fame of Herefordshire poultry was at its height years ago when prizes were given at the Christmas market for the best specimens, and spectators as well as buyers came from long distances. These prizes were discontinued about ten years ago, when some of the unsuccessful exhibitors contended they were as deserving of the prizes as the successful exhibitors. The absence of the prizes has since been continually regretted. A new generation of stallholders have since then entered the lists, and maintained the good name which the old stallholders obtained for good poultry. The attention previously paid to fattening for the Christmas prizes was directed more to the breeding; and the poultry, minus much of the usual fat, became still more appetising at the dinner table, and profitable also to the consumer, for it is stated there is considerably more flesh-forming matter in poultry than in butchers' meat. At this year's great Christmas poultry market, which was held on Wednesday last, money prizes as undermentioned were once more given for the best poultry, not simply for select birds that might be chosen by their owners for competition in the hop room as in years gone by, but for birds pointed out in the open market by an able judge." Stalls were held by about one hundred farmers' wives and daughters, and on some of them there was a magnificent display. On one there was 105 head of poultry. One purchaser is said to have taken away a ton of poultry. The largest Turkeys weighed about 30 lbs., the largest Geese about 16 lbs. The prices obtained for Turkeys, 1s. to 1s. 3d. per lb.; Geese, 8d. to 10d.; Ducks, 6s. to 10s. couple; fowls, 4s. 6d. to 8s. and 10s. couple; eggs, eight and nine the shilling.

— DEATH OF MR. MECI.—The death is announced of Mr. J. J. Mechi, the well-known agriculturist, whose recent failure evoked so much sympathy. It took place on Sunday last at Tiptree Hall, Essex. Mr. Mechi, the son of Giacomo Mechi, a citizen of Bologna, who early in life settled in England and obtained a post in the household of George III., was born in London in May, 1802, and was trained in a mercantile house engaged in the Newfoundland trade. By his industry and the profits derived from an invention of his own he was enabled to start in business as a cutler in 1827, and between 1830 and 1840 realised a fortune by the sale of a razor strop which bore his name. In the last-mentioned year he bought the farm at Tiptree Heath, consisting of about 130 acres of inferior land, and forthwith began his farming experiments by deep draining and the application of steam power. He was laughed at by his neighbours as an enthusiast, but he persevered, and by-and-by made the farm pay a handsome profit. In 1856 he was appointed to the shrievalty of London, and was elected an Alderman the following year. About this time

he was presented with a testimonial of the value of £500, subscribed by noblemen and gentlemen interested in scientific agriculture. He was a Juror in the Department of Science and Art at the Great Exhibition of 1851, and at the Paris Exhibition four years later he was specially sent out by the English Government. After eight years' service as Alderman of London he resigned his gown, very much against the wish of his constituents. Mr. Mechi was the author of several works on agriculture, the most popular being, perhaps, "How to Farm Profitably," of which many thousand copies were sold. Doubts have often been cast on the pecuniary results of Mr. Mechi's farming, but in his circular made public last week he reaffirmed that they were satisfactory, and declared that his failure was due to losses on his London business.

— A NEW CROSS-BRED TABLE FOWL.—The following letter of a correspondent of Mr. W. B. Tegetmeier's has been published in a contemporary:—"I have long thought whether one could not start a new and better race of poultry for table purposes. I farm some 300 acres of land, and have tried various kinds. Dorkings were always favourites; but though I have had no difficulty of getting very large birds, they were undoubtedly bad to rear, few hatching out, and some of these dying. I now keep at my farm buildings, at 600 feet elevation on limestone, Houdans, about thirty hens at the beginning of the season, and here, just where the red clay ends, about as many Dark Brahmas. These breeds fit in well. The Brahmas lay all winter and the Houdans all summer, and the Brahma hens hatch out the Houdans for table. Being able to keep two breeds, and being obliged to have heavy fowls here close to the garden, this is the best combination I have come across. But Houdans are not so good to eat as Game, and I think not as Dorkings. I have tried the Dorking and Brahma cross—tremendous birds, and the hens good-looking, but the cocks very ugly. Houdan cock and coloured Dorking hens made good early-maturing fowls; and, curiously enough, they were all jet black, and of very marked character as to comb, tail, &c. The reason of this letter is to ask whether it would not be better to cross the Dorking cock with Black-breasted Red Game hens, inasmuch as the latter are said to be so much better layers than Brown Red, and therefore more likely to produce a laying as well as a fattening breed—a great desideratum."

— MALICIOUS INJURIES AT POULTRY SHOWS.—Seldom has a more dastardly act been brought to light than that disclosed last week by the examination of the contents of the stomachs of the birds which died at the Vale of Severn Society's Show. On the second day of the Show the occupants of five pens of prize Bantams were observed to be ill, and before the end of the Show the birds were all dead. The stomachs were sent for analysis to the public analyst for Northumberland, and he has reported that the birds died from the effects of phosphorus given in the form of paste. A reward of £10 is offered by the Society for such information as will lead to the apprehension and conviction of the persons who administered the poison. We trust that they may be discovered and punished as they richly deserve.

SUCCESSFUL BEE-KEEPING.

THE recorded results of bee-keeping in Scotland this year are very satisfactory and encouraging. The records of such results will do good by stimulating the hopes and renewing the energies of many apiarians on this side of the Tweed. While the records mentioned, coming as they do from three separate counties, maintain the renown of Scotland for successful bee-keeping, it is to be hoped that they will sharpen the discernment of English bee-keepers. Though we have had many unfavourable seasons for honey during the last ten years, especially in the midland and north of England, let us hope that good seasons and times will come, and that we shall be prepared and ready for them when they come. In the recorded results we are going to review we have a wealth of evidence that bees are wonderfully industrious, that bee-keeping is interesting and profitable, and that, though much depends on the skill and attention of the apiarian, success may be attained with all kinds of hives. The secret of successful bee-keeping is very simple. Some days ago I received a letter from one of the most careful and successful bee-keepers I have ever known. He conveys his secret of success in few words, as follows:—"As for profitable management, the main thing is to study bees thoroughly, give them room enough, feed them when they require it, and give no more than they need. Bees will

gather and make as much honey in a flour barrel as in the finest bar-frame or Stewarton hive ever made. With fine weather and plenty of room bees will work well anywhere, even hanging on a tree.

This is the statement of Mr. James Rennie of Carluke, one of whose hives with its swarms rose this year to the gross weight of 474 lbs. These figures were offered to the bee-keepers of Great Britain, and comparisons were invited. Mr. Anderson of Dalry, who is a well-known and successful Ayrshire bee-keeper, comes to the front with a higher figure still—namely, 481 lbs. from a Stewarton hive, and its swarms belonging to Mr. James Crawford of Arran. I cordially thank Mr. Anderson for the record of such work. Mr. Raitt and Mr. Mann of Perthshire give us the receipts of honey and money from a bar-frame hive belonging to Mr. Mann. I am glad they have done so. From this bar-frame hive 122 lbs. of honeycomb in 1-lb. sections and 30 lbs. of extracted honey were taken, and 40 lbs. of honey left for the bees to winter on. We have here good results from a bar-frame hive. I confess to a little astonishment that Mr. Mann after all "considers this has been a poor honey season." The comb and honey were sold for £9 11s. Mr. Anderson speaks of the season as a "most productive one," and hundreds of Scotch apiarians have found it so. We have now before us the record of results most encouraging and satisfactory from three different kinds of hives. I am greatly pleased with them all. If viewed in a good light perhaps we should find in them more likeness than contrast.

When the weight of the straw hive first appeared Mr. Raitt wrote to me asking or suggesting that the profits or money value of the contents be given. He was told that no figures of profit had come from Carluke, and therefore I could not give them. When the letter of Messrs. Raitt and Mann was published containing the money profits of the bar-frame hive, it was sent in a letter to Mr. Rennie, who returned it with a reply in which he says, "I object to giving money particulars about my bees for publication, although I could tell a far greater fact than Mr. Mann, and plenty of other bee-keepers in Carluke could do the same." This is certainly encouraging to all apiarians. Having Mr. Mann's profits before us we may compare the results. Mr. Mann's hive yielded 122 lbs. of comb and 30 lbs. of run honey. The comb at 1s. 4d. per pound would realise £8 2s., and the honey at 1s. per pound would raise the amount to £9 12s.—only 1s. more than was realised. The prices obtained by Mr. Mann are rather disappointing to me, for I was told two years ago that the honeycomb of sectional supers was sold at 1s. 8d. per pound. If the comb in sections 1 or 2 lbs. in weight does not fetch a higher price than comb in common supers the introduction of sectional supers will be of very little value. The Carluke bee-keepers obtain 1s. per pound for run honey and 1s. 3d. for honeycomb in supers. These prices have been obtained regularly for fifty years.

I now come to the interesting point of comparing the money value of the outcome of the Stewarton hive weighing 481 lbs., and the straw hive weighing 474 lbs. I do not know the weight of the hives and bees in either case, but let us suppose that the bees and empty hives would weigh in each case 120 or 130 lbs. I have no disposition to overweigh or underweigh anything. After the weight of hives, boards, and bees have been taken from the gross weight one can pretty accurately estimate the weight of honey in the contents of the hives. Every 7 lbs. weight of contents yields 5 lbs. of honey. At this calculation the honey of the Stewarton hive would weigh about 250 lbs., and the honey of the straw hive about the same. Now 250 lbs. of run honey at 1s. per lb. gives considerably more than Mr. Mann's £9 11s.; and if much of the contents were sold as honeycomb at 1s. 3d. per lb. the bar-frame hive would be found farther behind still. If the honey and profits of the three hives could be fairly weighed the probability is great that the bar-frame hive would rank third best. Notwithstanding I gladly admit that both Mr. Raitt and Mr. Mann are advanced, clever, and successful bee-keepers. In my opinion Mr. Raitt has done more to improve the bar-frame hive and manage it practically and scientifically than any other person in Great Britain. In the excess of his enthusiasm for "modern bee-keeping" as he calls it, he appears occasionally to go a little too far. For instance, he and Mr. Mann say "that the time for pitting straw hives against bar-frames was over long ago." May I ask, How long ago? When and where has the bar-frame hive carried off the palm of greatest weight or profit? Mr. George Fox of Kingsbridge, Devon, ventured to fit the straw hive at the Crystal Palace shows against all comers, and on every occasion he carried off the honours against the bar-frame hive.

About two years ago Mr. Ollerhead delivered a lecture on bees at Wimbledon, which was published in many periodicals. In this lecture Mr. Ollerhead says, "he prepared twenty hives for winter, some of them were bar-framers, some Stewartons and

Carr-Stewartons, and some Pettigrews. To my mind the best hive for quantity of honey, either in the comb or in supers, is the large straw hive. I have visited every show of the British Bee-keepers' Association, and have so far failed to find any hives better adapted for the profitable management of bees than the Pettigrew hive." From it, he says, "he has taken considerably more than the returns from any other hive on the same ground and under the same treatment." It distresses me to quote such a passage as this in which my own name is mentioned, but I do so now in the interests of the bee-keeping community. So far as my reading and observation extend there is very little room for the assumption of superiority. Two years ago Mr. Raitt informed me that he had made £40 from twelve hives, and about a quarter of this sum was taken from one of them. His profits or income was at the rate of £3 7s. per hive. The same season some apiaries of straw hives at Carlisle made or yielded £4 6s., and two bee-keepers made at the rate of £5 per hive. Probably Mr. Raitt increased his stock.

In closing these remarks I thank Mr. Anderson for the record of the Stewarton hive at Arran, and Mr. Raitt for the report of the bar-frame hive at Blairgowrie. Most of all I thank Mr. Rennie for what he has told us. His few words contain the best teaching of all successful schools. If the readers of the Journal have any of the three hives in their gardens, and if they carry the simple lessons of Mr. Rennie into practice with energy, it is certain that they will become successful apiarians. The challenge of Messrs. Raitt and Mann will be noticed by-and-by.—A. PETTIGREW.

P.S.—In justice to Mr. Rennie and the straw hive I confess I forgot to state he told me in his letter that the weight of his hives was taken before the end of the honey-gathering, and that as some hives gained 6 and 8 lbs. each afterwards he thinks his sum total would have been 20 lbs. more if he had had time to weigh them again.—A. P.

CONGRESS OF GERMAN AND AUSTRIAN BEE-KEEPERS.

THE Exhibition being now complete I will attempt a description of some of the more prominent exhibits. At No. 1 in the catalogue was a list of a natural history collection belonging to Dr. Pollman of Bonn, who for years past has followed the excellent idea of fitting up a bee cabinet which enables the visitor to follow and to study a colony from its cradle to its grave. In this cabinet nothing which concerns bee-keeping and bee life seemed to have been omitted. All the enemies of bees which endanger their life or interfere with their work were there. Near the above interesting display was the stand of Mr. Aloys Anton Schlösser, of Ehrenfeld near Cologne, well known as an able bee-master as well as a cultivator of Apples and other fruit. This gentleman exhibited about 1000 lbs. of extracted honey in 137 glasses, gathered from White Clover, Buckwheat, and blue Cornflower. In addition to this he exhibited bee furniture he has had in use in his apiary for the last twenty years; also a cake of beeswax weighing 70 lbs., and a comb-holder with honeycomb. In the garden Mr. Schlösser exhibited four double or twin hives which have been in use for years inhabited by colonies of German, Carniolan, Italian, and Cyprian bees respectively, which were much admired.

The exhibits of Pfarrer Daniels of Troisdorf were both numerous and tastefully arranged. What particularly struck visitors were his beautiful casts of wax. His assortment of honey, perhaps one of the largest in the Exhibition, comprised honey gathered from the Cornflower, the Bird Cherry tree, White Clover, Seradella Rape, Gooseberries, Lime trees, Heath, and other flowers. The samples of honey shown by Mr. Urban Weissweiler, schoolmaster of Dransdorf near Bonn, were also very good. Mr. Carl Regener, mechanical engineer of Bayenthal near Cologne, exhibited an observatory hive containing four combs placed vertically with a colony of Cyprian bees headed by a fine young queen. This was the only hive with living bees in the hall, and very closely resembled those commonly exhibited in this country. The bees found exit to the garden through a hole in the window-pane, a long tunnel covered with glass enabling the visitors to watch the labourers passing out and in. Mr. Regener had other beautiful objects—a splendid assortment of honey, in the midst of which is a crystal bowl of very fine honey taken from the comb by means of the extractor. He also showed a large quantity of bee furniture.

Almost all the hives shown were of straw and had small frames. These frames are generally placed across the entrance; the back opens so that they are drawn out either with the hand or with a pair of pincers constructed for the purpose, and are considered by German bee-keepers easy of manipulation. There were a great number of them very similar in form. There was, however, one frame hive of wood exhibited by Mr. F. Koester of Simburg, of very ingenious construction. It was something like a large Huber frame hive, and the frames were kept close to each other by means of two iron rods screwed tight with bolts. This gentleman had been living in America, and returned to his native country imbued with inventive ideas, for he also produced a honey-extractor of novel construction, the motive

power being simply friction. By drawing a long piece of wood against the wheel great rapidity and ease of motion were obtained. Mr. L. Eyllenfeld of Frankfurt had a very ingenious hive tenanted by living bees in the garden, very much like Gravenhorst's, with the dome-top frames. These drew out bodily at the side, and run on rollers very smoothly, and the frames are easily drawn out and returned. Dr. Dzierzon exhibited an Italian queen, which was priced at 12s. The bees were in a small glass case, and covered only one side of the comb. They were bright-coloured bees, and the queen a fine one. Herr Vogel had two cases of Caucasian bees with distinctive marking. These bees, like the Carniolan, are valued for their docile character.

The show of honey-extractors was large; some of them of novel and ingenious construction. Many wire masks to protect the face whilst manipulating found places on the table, also perforated zinc with three-sixteenths of an inch openings in considerable quantity, as well as cages for imprisoning the queen when the honey-gathering season is in full force, so that the cells may not be filled with brood, but with nectar. This mode of checking the queen in using her great functions of egg-laying is occupying much attention in Germany, and will no doubt also claim the increased attention of English bee-keepers. By a judicious regulation of the vast multiplying powers of the queen sufficient bees may be in the hive to keep up its strength, and at the same time not become so overpowering in numbers as to swarm or crowd and hang at the entrance, thus to impede the working of the bees, which in the ordinary course is so frequently the case. In German apiaries run or extracted honey is more generally produced than super or comb honey. This, no doubt, is so because honey in June is the more marketable article.

Although bee-keeping in the district of Cologne is said to be very much neglected, nevertheless many excellent things were to be met with from this neighbourhood. Even envious tongues could not but speak well of the glass bell on stand filled with honeycomb, of the samples of wax, the honey in glass jars, and the tasteful arrangements of the exhibits of Mr. Henry Beckers of Cologne. The same remark applies to the produce of bees and the bee furniture of Mr. Nicholas Assenmacher, jun., likewise of Cologne. The latter exhibited also under glass, hermetically closed, as a specimen a comb containing foul brood. I might further mention the following exhibitors—Mr. Von Der Goo, schoolmaster of Steinfield in the Eifel, heath honey in large combs; Mr. George Büsch of Harxheim near Mayence, a very large glass bell of fine honeycomb; Mr. Otto Schütz of Buckow, a large quantity of comb foundation, very well manufactured, and some was on wood. Many other exhibits might be mentioned, but perhaps the above will suffice to illustrate the general character of this interesting exposition of bees and the apparatus connected therewith.

The articles I exhibited were those well known as manufactured and sold by my firm; our safety smoker, Mr. Cheshire's "rakes" for fixing comb foundation in frames, with dozen elegant American section of honeycomb from Mr. Cowan's apiary, were among the collection which attracted much attention as illustrative of English appliances in bee-keeping, and for which I was awarded a silver medal.—ALFRED NEIGHBOUR.

(To be continued.)

REMARKS.

19th.—Stormy with slight rain early part of the morning; fine after 11 A.M., with bright sunshine; overcast evening.
 20th.—Rain during night; snow commenced at 0.45 and continued until 3 P.M.; damp and cold rest of the day.
 21st.—Fine, bright, and cold; slight fog in evening.
 22nd.—Overcast with steady rain until 5 P.M.; fine starlight evening.
 23rd.—Very fine and mild; rain in evening.
 24th.—Fine early; rain from 8 till 9.30 A.M.; very bright and fine; from 10 A.M. till 2 P.M. overcast and very dull for an hour; clear and bright till 4 P.M., then heavy shower; fair but damp evening.
 25th.—Fine, bright, and clear throughout; almost uninterrupted sunshine from sunrise to sunset.
 A wet week and rather cooler than the previous one, but still slightly above the average temperature.—G. J. SYMONS.

COVENT GARDEN MARKET.—DECEMBER 29.

THE holidays have completely checked business, nothing of any note taking place in our market. The prices remain the same as last week.
